Architect. Lecturer on Architecture. Author of *A History of English Brickwork.* } Brickwork.
- N. U.** NORMAN UNDERWOOD.  
Chemist, United States Bureau of Engraving and Printing, Washington. Author of *Chemistry and Technology of Printing Inks.* } Carbon Paper.

- O. SYDNEY OLIVIER, 1ST BARON OLIVIER OF RAMSDEN, P.C., K.C.M.G., C.B., B.A., LL.D.  
Secretary for India, 1924. Late Governor of Jamaica. Author of *White Capital and Coloured Labour*; *The Anatomy of African Misery*; *The Empire Builder*. See biographical article OLIVIER, S. } **British Honduras (in part).**
- O. L. D. OLIN L. DEMING.  
Former Head of Publicity and Advertising Department, American Can Company, Chicago. Formerly edited *The Food Bulletin*; *The Canner* and *National Canner*. } **Canning (in part).**
- O. W. H. O. W. HOLMES, B.A.  
Reference Staff, New York Public Library (American History Division). Editorial Staff (New York), 14th Edition, *Encyclopædia Britannica*. } **Carver, Jonathan.**
- P. A. K. PRINCE PETER ALEXEIVITCH KROPOTKIN.  
Russian Geographer, Author and Revolutionary. Editor for the Jura Federation of *Le Révolté*. Author of *L'Anarchie: sa philosophie, son idéal*; *The State, Its Part in History*; *Memoirs of a Revolutionary*; *History of the Great French Revolution*. See biographical article KROPOTKIN, P. A. } **Bulgaria, Eastern.**
- P. A. M. PERCY A. MARTIN, A.M., PH.D.  
Professor of History, Stanford University, Palo Alto, California. Secretary of the Brazil Committee of the Pan-American Financial Conference, Washington. Author of *The Republics of Latin America*; *Latin America and the War*. } **Brazil (in part).**
- P. B. PIERRE BERNUS.  
Foreign editor of the *Journal des Débats*; Paris correspondent of the *Journal de Genève*. Chevalier of the Legion of Honour. } **Briand, Aristide.**
- P. La. PHILIP P. LAKE, M.A., F.G.S.  
Lecturer in Physical and Regional Geography in Cambridge University. Formerly of the Geological Survey of India. Author of *A Monograph on British Cambrian Trilobites*; etc. Translator and Editor of *Kayser's Comparative Geology*. } **Cambrian System.**
- P. L-B. PERCY LAZARUS-BARLOW, M.D.(CANTAB.)  
Pathologist to the East Sussex Hospital, Hastings. Formerly Assistant Bacteriologist, Metropolitan Asylums Board and Pathological Registrar, the Middlesex Hospital. } **Calculi.**
- P. Mo. PHIL MOORE, E.M.  
President, Nova Scotia Guides Tournament Association, Nova Scotia. Author of *Gun and Rod in Canada*; *Slag and Gold*. } **Canoe (in part).**
- P. M. R. P. M. ROXBY, M.A.  
Professor of Geography in Liverpool University. } **Canton.**
- P. P. PERCY PITT.  
Director of Music, Royal Opera House, Covent Garden, London; British Broadcasting Corporation. Director, British National Opera Company. Composer of numerous orchestral works. } **Broadcast Music (in part).**
- P. P. E. CAPTAIN P. P. ECKERSLEY, M.I.E.E., F.I.R.E.  
Formerly Chief Engineer to the British Broadcasting Corporation. } **Broadcasting (in part).**
- R. B. RALPH BOWN, M.E., PH.D.  
Department of Development and Research, American Telephone and Telegraph Company, New York. Past President, Institute of Radio Engineers. } **Broadcasting (in part).**
- R. B. D. ROLAND BURRAGE DIXON, PH.D.  
Professor of Anthropology at Harvard. Author of *Oceanic Mythology*; *Racial History of Man*; *The Building of Cultures*. } **Calchaquian.**
- R. C. E. L. RICHARD C. E. LONG, B.A., F.R.A.I.  
Author of *Maya and Christian Chronology*; *The Age of the Maya Calendar*; etc. } **Calendar: Maya and Mexican.**
- R. Co. REGINALD COUPLAND, C.I.E.  
Beit Professor of Colonial History, Oxford University. Formerly Fellow and Lecturer in Ancient History at Trinity College, Oxford. Author of *The Study of the British Commonwealth*. } **British Empire (in part).**
- R. D. RANDALL DAVIES, F.S.A.  
Sometime Art Critic to the *Academy*, *Westminster Gazette*, *New Statesman* and *Queen*, London, and secretary to Joseph Pulitzer, owner of *New York World*. Author of *Six Centuries of Painting*; *Monographs on Velasquez*; *Reynolds and Romney*; etc. } **Caricature (in part).**
- R. D. D. RALFE DAVIDSON DAVIES.  
Captain Royal Engineers. Experimental Officer, Experimental Bridging Establishment, Christchurch, Hants. } **Bridging, Military.**
- R. G. S. ROBERT G. SPROUL, B.S., LL.D.  
Vice-President, University of California, Berkeley, Calif. } **California, University of.**
- R. H. R. SIR R. HENRY REW, K.C.B.  
Board of Agriculture and Fisheries, 1898, Assistant Secretary, 1906-18. President, Royal Statistical Society, 1920-2. Secretary to the Ministry of Food, 1916-7. Chairman, Inter-Departmental Committee on Unemployment Insurance in Agriculture, 1925-6. Author of *A Primer of Agricultural Economics*. } **Butter (in part).**
- R. I. P. REGINALD INNES POCOCK, F.L.S., F.Z.S., F.R.G.I., F.R.S.  
Natural History Editor of *The Field* and Temporary Assistant in the Zoological Department of the British Museum since 1923. } **Carnivora (in part).**
- R. J. G. REGINALD JOHN GLADSTONE, M.D., F.R.C.S., L.R.C.P., F.R.S.E.  
Reader in Embryology and Lecturer in Anatomy, King's College, University of London. Author of numerous articles in the *Journal of Anatomy*; etc. } **Brain (in part).**
- R. K. ROLLIN KIRBY.  
Editorial Writer and Political Cartoonist of *The New York World*. } **Cartoon (in part).**
- R. L. ROBERT LIEFMANN.  
Professor of Economics and Finance, University of Freiburg im Breslau. Author of *Kartel and Trusts*. } **Cartel.**

## FOURTEENTH EDITION

### VOLUME 4 BRAIN TO CASTING

**B**RAIN. If by physiology of the brain we mean the study of the biological function of that organ, the state of exact knowledge regarding it is still extremely inadequate, although there exists a vast body of detailed fact. General inferences as to function drawn from morphological and phylogenetic data are therefore a permissible and welcome help although often of the nature of suggestion rather than demonstration. It is with the vertebrate brain, that the following account will be concerned; and the human brain constitutes the climax of the evolution of the vertebrate brain at present, though not, of course, in finality. The past history of the brain traced in the vertebrate stock assists comprehension of the function of the human brain.

**The Vertebrate Brain.**—In the vertebrate a median lengthwise nerve-cord threads the fore-and-aft series of its segments; the brain is the anterior or head portion of the nerve-cord; the rest of the cord being the "spinal-cord." In the most primitive of all vertebrates, amphioxus, which must be a close relative of the prime ancestor of the vertebrate stock, that part of the nerve-cord lying at the front end differs so little from the rest that there is nothing which can properly be termed "brain." But in amphioxus there is likewise so little differentiation of the front end segments of the creature itself that nothing there can properly be termed a "head." The existence of a brain is thus correlative with the existence of those special developments, *e.g.*, specially developed receptor-organs for distance-stimuli (tele-receptors) such as olfactory, photic, etc.; and for feeding apparatus, etc., which so commonly at the forward end characterize that end and form a head. The next earliest living fragment of the vertebrate ancestral line is a greatly higher though still quite primitive form, petromyzon. This possesses at its front end distance-receptor organs and a head. The corresponding anterior segments of its nerve-cord are specialized and developed as a rudimentary brain. As to which may be the *propter hoc* of this correlative growth and how far the neural development (brain) may be secondary or not to the development of the non-neural factors in the cephalization is difficult or impossible to know.

The brain is, however, always that part of the nervous system which is constructed upon and evolved alongside of the distance-receptors. The importance of this conjunction in this matter is that it means ability on the part of the animal to react to an

object when still distant and allows an interval for preparatory reactive steps, and this can go far to influence the success of its behaviour in regard to that object. The reactions initiated and guided by the distance-receptors are all steps towards final adjustments, which latter are consummations often of critical importance for the existence of the animal (*e.g.*, attainment of food) or of its species (*e.g.*, fertilization). This time-interval and its series of steps, along with the vicissitudes of relation between things of changing position reacting one on another at a distance, conspire to give to the distance-receptor reflexes a multiformity and a complexity unparalleled by the reflexes initiated from other receptors. This interval affords much more copious opportunity for adjustment and side-connection as occasion demands. It gives freer play for the affixing of new-conditioned (*i.e.*, individually-acquired) reflexes to the primal inborn reflexes. Further, the time-interval allows opportunity for variations of behaviour to be failures and yet recovered from, and conversely, allows greater chance for successful reaction-variants to be selectively preserved.

**Course of Vertebrate Evolution.**—As we pass from lower vertebrates to higher we find, broadly taken, a progressive increase in the relative size of the brain. This fact stands related to two features which characterize the vertebrate evolution, and seemingly also that of other phyla as well. One of these features is that, broadly speaking, the course of vertebrate evolution has tended to produce a more and more unified individual, an individual of greater functional solidarity, although still consisting of individually living cell-units. Consistently with the two main biological requisites of the individual animal life, namely its preservation and that of its species, the closer functional welding of the parts of the animal individual into an integrated whole seems, as we look along the vista of geological time and of geographical spread, to have been a steady outcome of evolution.

The other feature is not unrelated to the foregoing one. It is, that evolution, though with chequered history, has resulted in animal forms possessing successively greater dominance over their environment. Organisms are commonly spoken of as "lower" and "higher." The "lower" are usually the simpler, the "higher" the more complex; but the "lower" need not the less perfectly fulfil their primary biological requisites, preservation of self and species. There are brachiopods which have without visible change maintained themselves in and upon their environment from the era of the earliest fossil-bearing rocks till to-day, and they are "lower" animals. Such commerce with and maintenance in the

environment must be as admirably adjusted as can be any imaginable so far as concerns persistence of life. Yet, in the course of time, evolution has produced animal forms which pursue a far richer and more manifold commerce with the environment and some of these dominate the environment more variously and extensively than others, including their own ancestry, have done. In this sense they are "higher" forms." The earliest animal forms have included none of these highest, and some of the very latest are also the very "highest" forms achieved. As judged by dominance of the environment man, although quite a recent form, is the highest as yet. The key to this evolutionary feature is furnished largely by the evolutionary history of the brain and its functions.

**Increased Integration.**—A factor, and in some respects a decisive one, both in the accomplishment of greater functional solidarity of the animal and of its higher mastery over the environment, is the progressive development in the nervous system of a dominant part. The organization of the central nervous system is thus enhanced as an integrator of the animal in its life of external relation. The integration combines into great unitary harmonies, reactions originally scattered and local and semi-independent acts. It organizes the several segments and segmental regions into a well-knit individual. The establishment in the central nerve-cord of, so to say, a headquarters station for receipt of calls from many directions and for dealing through subsidiary parts of the nervous system with the motor machinery of the animal as a whole, imbues the organism with individuality of a higher kind. It is this that the advent of the brain foretells. The progressive development of the brain increasingly secures advantages.

The success seems partly a matter of mere increase of centralization. The receptor apparatus of the head gets increased coordinative guidance of the body. The body tends to become a locomotor, and later a secondary prehensile train and a digestive appanage attached to the head, with, as inalienable possession, the reproductive organs. The brain in this respect merely takes with further specialized success the general rôle assigned to the nervous system from its earliest appearance and onward throughout evolutionary history, namely, the welding of the body's component parts into one consolidated mechanism facing as a united entity the changeful world about it. The work of this kind done for the "higher" animal by its brain presents the acme of animal integrative achievement. Hence is it that each of us, though made up of myriads of cell-lives individually feeding and breathing, and of manifoldly differing activities, constituting scores of organs, yet appears to himself a single entity, a unity experiencing and acting as one individual. That the particular bodily system which is specialized for integration, and whose sole function is integration, and that that portion of it where integrative function is at its highest should be the seat of mind, even from the dim mental beginning, and that mind should remain there localized and despite all mental growth stay restricted in seat there along millions of years, on into ourselves to-day, indicate the scope and crowning importance of nervous integration and the brain.

**Control of Environment.**—In regard to attainment of wider mastery over the environment, no less than in respect of organizing the individual, has phylogenetic development of the brain played a decisive part. The more numerous and extensive and the better co-ordinated the responses made by a creature to the actions of the world around upon its receptors, the more completely will the bundle of reflexes (which from one standpoint the creature in its life of external relation is) figure the complexity of the environment and meet widely and successfully its situations. And at the root of the success of the brain as an integrator there lies something more than is represented in its expressing merely a more highly organized centralization.

Over and over again in the evolution of the brain there is instanced the importance, for the process of integration, of connecting together nerve-structures which might or do react concurrently but are originally unconnected. Concurrent activity of such related nerve-paths promotes actual architectonic welding of them (neuro-biotaxis, Arisus Kappers, 1908). A responsive group of neurons tend to be drawn toward their dominant stimulators.

The simultaneous components of a "reflex-figure" (Sherrington, 1906) tend to stamp in a neural pattern. The functional "reflex-figure" with its simultaneously reacting parts proceeds along with (as its structural counterpart) a neural pattern which may become innate or be an individual acquirement (*e.g.*, mammalian cortex).

A keystone of the principle of integration is that the concurrent activity of related parts results in more than the simple sum of the activity of the separate component parts. Thus, in psychical integration, the single touch gives experience of itself alone. But a double simultaneous touch (*e.g.*, compasser) gives experience of two touches, and, which is new, an untouched space between. The integration results in more than the mere sum of the components. Again, the unocular field gives experience of some amount of "depth"; but when in combination with the other unocular field to a binocular, there is yielded such an enhancement of the third dimension as amounts to a new result, the "depth" of stereoscopic vision. So with the visual integration illustrated by the "steps" figure, it is much more than its component lines, because whether the steps appear to "overhang" or "run up" there is always a foreground and background, *i.e.*, the whole presents more than the parts, and constitutes a "situation" with "relations." And in the vertebrate after advent of the brain the animal's reactive behaviour shows in increased measure the important quality of modifiability by experience, using this last term without of necessity any psychological connotation. Late in vertebrate development in a restricted number of forms, all mammalian and nearly related one to another, and relatively very recently evolved, this modifiability of behaviour has become greatly more effective. Its highest outcome appears perhaps as the rational guidance of human conduct.

It is not of course that either the fuller integration of the individual animal or the higher animal's wider dominance of the environment are the result entirely of the brain or of the cerebral adjunct "mind." Contributory to the latter result has been the mechanism (partly nervous) for ensuring a constant temperature-environment for the tissues of the body, enabling the individual's activity to be uninterrupted by season, and largely independent of latitude; also the gestation arrangement which protects the young within the mother until a relatively late stage, providing exceptional pre-natal care for the offspring. Nevertheless the extreme importance of the contribution by the brain is shown by the degree of dominance over the environment obtained by man as compared with that of other, even the highest other, placental mammals.

The vertebrate brain consists of a fore-and-aft series of three portions, the fore brain, mid brain and hind brain.

**Hind-Brain.**—The hind-brain, as traced upward from the lamprey, shows two main functional divisions. Of these, one, the basal, closely resembles the spinal cord of which it is the continuation in the posterior head segments. In air-breathing vertebrates this basal portion contains a "centre" regulating the movements which ventilate the lungs. This mechanism presents the interesting physiological feature that while "reflex" in the sense of being driven and controlled by nervous impulses arriving at it by well recognized afferent nerves, it is also activated and partly regulated by stimuli arising autochthonously within it. This intrinsic stimulation is perhaps generated and is certainly influenced by the chemical condition (degree of acidity) of the blood. Another centre in this basal part of the hind-brain is, in higher vertebrates, one which influences the general circulation of the blood, by regulating the contraction of the muscles of the arterial tubes and to some extent of the heart itself. There lie also in this region reflex centres which maintain postural contraction of the extensor muscles of the limbs and trunk in response to passive stretch of these muscles. In the erect attitude of the animal these muscles are subjected by the weight of superincumbent parts to stretch and they are termed antigravity muscles; and this hind-brain region therefore executes a crude reflex standing, traces of which can be executed even by the isolated spinal cord itself (dog). Further forward still this part of the hind-brain receives the nervous impulse from the labyrinth-organs, and enables still more perfect reflexes of standing.

**Cerebellum.**—The hind-brain has further an important roof-portion, the cerebellum, so called because in man, large and with paired lobes, it seems, to gross inspection, a small replica of the great cerebral hemispheres in front. The cerebellum has its cradle, ontogenetically and phylogenetically, in the primary receiving stations of the receptive nerve from the labyrinth, a proprioceptive organ largely controlling the postures of the head in regard to the vertical (line of gravity) and the posture and motions of the body in regard to motions of the head. The primitive cerebellum rests further on spinal nerve-tracts from the proprioceptors of the body muscles and limb muscles. Traced up from the fish through amphibia and reptiles to birds the relative size of the cerebellum differs in even nearly allied groups, but bears evident proportion to range and power of skeleto-muscular motility. In forms which crawl and creep it is quite small, but in the great swimmers and fliers it is large, even very large. With the mammalian series, however, a steady progress in cerebellar size occurs along with ascension to higher forms and culminates in the ape and man. Two large lateral developments are added to the pre-existent, unpaired median portion. Each of these lateral additions is functionally an annex of the new mammalian neopallium of the contralateral cerebral hemisphere, and with this latter go considerable developments in the median (palaeo) cerebellum also. The surface sheet of the cerebellum has a peculiar and characteristic minute structure, which is both in the palaeocerebellum and in the neocerebellum, although the history of the two seems so different and though the genesis of the neocerebellum is separated by some millions of years from that of the palaeocerebellum. To all appearance the neural chains of the cerebellum are a collateral path which, as regards those of the palaeocerebellum, belongs to the afferent limbs of reflex arcs actuating skeletal movements, but as regards those of the neocerebellum belong to the efferent central path of "volitional" movements.

The excitability of the cerebellar surface by electricity has been denied, but recent studies confirm that, as formerly claimed (Ferrer), considerable areas of the surface are truly excitable by electrical stimuli. The excitable field is palaeocerebellar (Ingvar, Bremer) and causes inhibitory relaxation of certain active postures, e.g., of extension-abduction of limb (Bremer, Miller and Banting, Sherrington). Destruction of the palaeocerebellar region which receives proprioceptive spinal tracts causes exaggeration of the stretch-reflexes of the limb-extensors (Bremer). Disease with cerebellar defect in man produces its most obvious detectable results in the field of willed muscular acts. The accuracy of execution of the movement is impaired by overshoot, abruptness of start and stop, ill-sustained contraction, and undue liability to fatigue. Cerebellar ataxy seems to contain the following three factors (Walshe), diminished fineness of postural adjustment, excessive intensity of postural activity, and complication of the two foregoing by voluntary efforts at correction.

**Function of the Cerebellum.**—Acute unilateral damage of the cerebellum in man brings as characteristic symptoms (1) tendency to fall sideways toward the side of the injury, especially if the eyes be closed; (2) the hand in reaching toward a point goes too far or stops too short; (3) in alternating movement the limb on the side of the lesion cannot alternate its phases with normal quickness and accuracy, it starts late and ends late for each phase; (4) with eyes shut the limb tends unconsciously to slip from an adducted into an abducted posture; (5) the position of the limb is often misperceived, its degree of abduction being underestimated. There is, however, no impairment of skin sensations or of pain-sensation superficial or deep. Strangely enough, congenital absence, total or almost so, of the cerebellum has been authentically found in persons who have lived their lives without suspicion of any nervous defect. How the defect is compensated remains at present unanswered.

Obviously the function of the cerebellum is still obscure, although it is a large organ, weighing in man more than the entire spinal cord. Proprioceptive receipts seem at the base of palaeocerebellar function, and suggest for it an adjusting co-operation in the execution of muscular acts, the acts themselves being initiated and directed by other centres than the palaeocerebellum, probably

mainly those of the mid-brain. The neocerebellar function may be inferred to be similar in character to that of the palaeocerebellum but to be adjuvant to movements of a newer physiological order (voluntary), initiated and directed by the neopallium (cerebral cortex). The neopallium in activating these movements probably activates collaterally the associated neocerebellar co-operation. The status of the cerebellum in the motor acts seems merely that of an executive instrument of them; the purpose and object of them are none of its affair. Cerebellar reactions are unconscious. Its destruction entails no loss of sensation, although cerebellar disturbance may occasion some proprioceptive mis-perception.

**Mid-Brain.**—The mid-brain like the hind-brain is made up of centres intrinsically its own as well as of conducting tracts merely passing through it to connect centres extrinsic to it. Its main intrinsic apparatus is collected in its roof. This receives a great afferent path from the retina, and also from the receptive centres of the hind-brain and spinal cord. It distributes efferent paths to neighbouring motor stations in the neighbourhood, including those of the eye muscles; many of these paths decussate across the mid-line. It sends also some longer paths forward to the fore-brain and backward into the spinal cord. It has also rich intrinsic interconnections. By means of its mid-brain the mammal, even after destruction of the fore-brain, is able to execute and maintain the erect posture and with better adjusted muscular tone than by means of the hind-brain alone. It is able further to assume the erect posture from other positions passively imposed upon it. It can "right itself." The mere motor execution of these reflexes is a matter of high complexity. Maintenance of standing involves duly adjusted simultaneous activation of many hundreds of thousands of motor units. The "righting reflexes" themselves are "chain-reflexes." In a "chain-reflex" the result of a foregoing reflex's execution is to evoke execution of the next succeeding one. This means due and successive activations of appropriate different great combinations of motor units, reaching at last the "standing complex," which forms an equilibrium, and, until disturbed, an end-point.

The cat retaining the mid-brain but deprived of the fore-brain reacts to sounds, although without giving indication of the direction whence they come. The mid-brain is in fact a large "exchange" where messages from the retina are associated with those from various other receptive nerves of the head and, via the spinal tracts, from the body (especially skin). In responding to these messages the mid-brain uses efferent paths by which it can operate upon motor centres, especially of the eyes and mouth and also of the neck and body. Severe impairments of motility and of normal posture are therefore produced by injury of the mid-brain roof, but although relatively large in lower vertebrates it becomes relatively dwarfed in the mammalian brain. There is some evidence that in the course of vertebrate evolution along the mammalian branch, the intrinsic importance of the mid-brain as a dominating centre becomes smaller, not only relatively but absolutely. The supreme control of behaviour becomes located progressively more forward, passing from mid-brain (most fishes) to thalamus and striatum (reptiles and birds) and then to cerebral cortex (mammals).

**Fore-Brain.**—In the fore-brain four main constituents are strikingly distinguishable. They are, the thalamus, olfactory lobe, striatum and pallidum. The latter three belong to the end-brain, so-called because it is the actual terminal piece of the nerve-cord itself.

**Thalamus.**—Throughout the vertebrate series the thalamus is a structure for correlating messages relayed up from receiving stations corresponding with all the various classes of receptor-organs both of head and body; eminently so with the retinal, whence the term optic thalamus. Besides providing machinery for interconnecting these and bringing their receipts (Parsons) to bear on the motor centres of mid- and hind-brain, it is itself a relay station for transmissions to the striatum. Where as in mammalia the neopallium is large the thalamus becomes a relay station for routes thither, and on an enormous scale. In lower mammals it is subdivided into regions ("nuclei") each preponderantly representative of some specific set of receptors (retinal, auditory, tac-

tual-proprioceptive, etc.) and each in give-and-take connection with especially some one field of the neopallium (cerebral cortex). In higher apes and man the subdivisions become more complex still. The thalamus of lower vertebrates certainly mediates the simpler types of modification of behaviour by trial-and-error learning; after removal of the whole fore-brain the frog, for instance, is incapable of acquiring a very simple "maze" adjustment. But the feeding chain-reflex remains, the retinal reflex orientates the frog to the fly and if the fly moves again the simultaneous spring and snap reflex follows, to be followed if successful by the swallow reflex. The thalamus is of itself quite incompetent in the hen for the instinctive behaviour of the maternal uprearing of the chick.

In close association with the thalamus is an underlying structure, hypothalamus, among whose ascribed functions is nervous regulation of the mechanism (vascular, glandular, etc.) by which in animals of constant temperature (birds, mammals) the body temperature is maintained steady despite environmental changes, a result contributing enormously to evolutionary success. In addition to this so to say essentially vegetative function, the hypothalamic region is concerned with visceral nerve-relays, putting them in touch with taste and smell (from in front) relays. It is therefore relatively large in lower vertebrates, while the thalamus, analogous with it but in an exteroceptive and somatic rather than a visceral field, gains on it in higher vertebrates. In the bird the thalamic fore-brain independently of the cerebral hemispheres seems to operate large reflex reactions to noxa, to hunger, thirst, and temperature, and possibly elaborates mental concomitants of these. But even in the highest mammals tonic activities of the sympathetic, essentially a visceral, system are traceable to this region. The nexus between sympathetic and visceral reactions on the one hand and affective and emotional mental experience on the other makes the close relation between thalamus and hypothalamus the more significant.

The dog or cat deprived of fore-brain except thalamus does not react even when hungry to food placed before it. The muzzle has to be dipped into the food or the food put into the mouth for the feeding to occur. Food doctored with quinine, etc., is rejected. Nociceptive stimuli to skin, etc., evoke biting, barking, miaowing and withdrawal of the threatened part. Yet in all this defensive behaviour there may be little or no indication of the locality of the offending stimulus. The animal, it has been inferred, can experience "pain"; it is not, however, able to acquire the simplest conditioned reflex. Its behaviour is confined to the stereotyped inborn reflexes. Its reflex behaviour is modifiable, however, to the extent that having hurt one foot it limps upon three legs until the hurt foot is healed. Its reactions, indicative of "pain," may possibly be pseudo-affective reflexes without psychical adjunct. But there is evidence from clinical studies (Head) that "pain" is among the reactions of the thalamus. Affective and emotional disturbances have come to be recognized as part of the syndrome of thalamic disease. The inference is therefore that the cerebral seat of mind does in some measure include—and so to say overlap upon—the thalamus even in higher mammals.

**Olfactory Bulb and Striatum.**—Of the three great components of the end-brain (cerebral hemisphere) one is the olfactory bulb, the reflex centre for the organ of smell, whose afferent nerve is so to say the segmental nerve for this region. Another is the striatum, a large correlating centre, of easily recognizable beginnings in fish and of further development in reptilia. In birds it becomes the largest element of the hemisphere, whereas in mammals although large it is relatively dwarfed by the development of the pallium, especially the neopallium of higher mammals. Birds, therefore, offer best opportunity for detecting striatal function, the more so perhaps since in them the olfactory region is greatly reduced. In the pigeon destruction of the hemispheres other than the striata leaves the feeding, mating and rearing reflex acts, as well as walking and flying with avoidance of obstacles, intact, but open to occur with less discrimination of stimuli. Conditioned reflexes can be acquired and attached to the innate ones, feeding or "avoidance." But if the striata be destroyed, the hen loses irrecoverably her maternal be-

haviour of incubating and rearing. So, similarly, the hawk caged with mice turns its gaze toward them when they move, but on their ceasing to move reaction ceases on the part of the bird. Neither does their movement excite attack upon them. The bird will starve in presence of its natural prey. It seems clear that in birds the striatum operates complex though stereotyped behaviour and provides in some measure acquisition of individual modification (by experience) of such behaviour.

Passing to the lower mammals, the striatum is relatively smaller than in birds. Conformably with mammalian ancestry some of the striatum is ancient and olfactory and probably serves higher correlations of smell with taste and touch for locomotor and head reflexes involved in feeding. Another part, also ancient, receives exteroceptive and proprioceptive tracts (from thalamus) but no olfactory; it operates movements through an emissive path to the mid-brain. To these old parts there is a new addition of as yet undetermined function. The cat (Dusser de Barenne) with neopallium lost but striatum (and archipallium) retained, localized the direction of sounds. In man destructive disease within the striatum is thought responsible for the syndrome of *paralysis agitans*, characterized by tremor and tonic spasm.

**Pallium (Cerebral Cortex).**—In fish and many amphibia the pallium is non-existent or present but in traces. It exists clearly though rudimentarily in reptilia. In view of the great importance ultimately assumed by the pallium it is well to remember that in entire absence of a pallium, not only is complex instinctive behaviour, but also modification of innate behaviour by individual experience, clearly evidenced in fishes and lower amphibia, not to speak of invertebrata.

From early reptilian stock came, it is held, the mammalian stock, as did independently and somewhat later in geological time the birds. In the course of bird evolution the pallium has progressed little or not at all, perhaps in correspondence with the avian lack of olfactory development, the pallium tracing its origin partly to nerve centres for smell. In mammals on the other hand the pallium taken over with primitive potentialities has proceeded to large and ultimately in some forms (apes and man) enormous development. Hence a progressive divergence might be expected between the courses of development of behaviour in birds and mammals respectively. The progress of bird-behaviour to its highest types might be expected to show little *qualitative* difference from behaviour of the old palae-encephalic type. Comparison of birds with bony fishes finds in both groups a great diversity of specialized forms with specialized behaviour evolved by hereditary organization, behaviour highly and rigidly stereotyped and fixed in character and little imbued with individual plasticity. In this respect both groups resemble the insects. The fish, however, reveals more individual modifiability (e.g., docility) than does the insect; and the bird on the average leads individually a more diversified life and has more power for "conditioned" moulding of innate instinctive behaviour than have fish (Herrick). Yet, there is a similarity of the behaviour of the two. Nothing essentially new in behaviour, not even in instinctive type, sunders the later group from the earlier.

Mammalian behaviour, on the other hand, in its course of evolution reveals attainment of certain additional new types of reaction, types different perhaps even radically from anything palae-encephalic. Indications of this are the replacement in some respects of "trial-and-error" learning by methods of "seeing-through" or of "stopping-to-think" about a situation. Another is the "tool-dom," if one may so call it, of man. And there is the specific human behaviour involving concepts and symbolic-thinking and employing complex speech. Of all this the development of the pallium is the correlative.

**Neopallium.**—That pallium which the mammalian stock derived directly from its reptilian ancestry, is an associating mechanism for receipts relayed to it from olfactory organs on the one hand and receptive organs of the mouth and muzzle on the other. This, the archipallium, therefore promotes in some way the behaviour reactions in regard to feeding, including in that the food-finding. No sooner, however, has the mammalian career of the pallium been entered on than a further formation adds itself to

the archipallium. This is the neopallium, a correlation-mechanism of still more decisive and capital importance, destined in man to exceed in size the total rest of the central nervous system. In man it is the seat of all which is exclusively human in the mind. It is a structure in which are brought together paths from less comprehensive correlating centres, e.g., those of thalamus. The archipallium correlates receipts from the olfactory distance-receptor with others from the skin, mucous membrane and muscles of the mouth region. The neopallium working on a grander scale brings together receipts from all the various species of receptors, distance-receptors and others alike.

But it is never reached by any receptive nerve immediately; it is reached only through relay-systems which climb to it via successive correlating-mechanisms. The recept-patterns which enter the neopallium (cerebral cortex) are therefore always greatly changed from those furnished to the first receiving stations by the groups of receptor nerves themselves. Yet, as is clear in the more primitive mammals just as the thalamus shows some subdivision into regions individually concerned with receipts predominantly of one kind of source, retinal, auditory, cutaneous, etc., so in the neopallium connected with the underlying thalamus there are individual territories which receive patterns composed predominantly of receipts traceable to one kind—be it this, or that—of receptive source. There is thus some “localization of function” in the neopallium in correlation with some at least of the sets of receptor organs, or, psychologically put, some at least of the modalities of sense. Vision is an instance.

**Developmental Stages.**—It is of interest and a help toward broad evaluation of the place of the brain in the scheme of life to trace so far as we can, the steps in biological history that were specially momentous in favouring or determining the vertebrate brain's evolution onward to its capital development in man.

One of these steps is judged to have been the emancipation from an aquatic existence achieved partially by amphibia with conversion of paired fins into limbs, and development of lungs for air-breathing. The body's greater need for support in air than in water made of the limb a jointed motor prop for locomotion with movement of diverse direction and with fingers and toes for clasping and other use. The limb and the evolving nervous system conspired so to say to draw advantage from this. The conquest of the land completed by the reptilian was accompanied by relative increase of the fore-brain. The land we may regard as a habitat of more varied difficulty and opportunity. Yet, launched from that stock, the primitive mammal was completely equipped for a land existence. Its fore-brain as judged from primitive existent forms was able, and grew more so, to learn with fewer repetitions and better retention; not only so, but its warm constant body-temperature provided for cerebral and other activities uninterrupted by seasonal abeyance. One great branch of this stock, developing a mechanism (placenta) of nutrition and protection for the young within the mother's body (ultimately in the human case nine months long), entered into active and successful competition with other land-forms, and indeed upon great competition within itself. We learn, by comparison of the fossil members of this great group with its present members of similar kind, that even with regard to allied forms the cerebral neopallium has become relatively much larger since the early Tertiary period. That is to say that in this group the modern individual has relatively more neopallium than had its ancient ancestor of like form and body bulk.

**From Sub-human to Human.**—The ancestry proper of man is thought traceable to some shrew-like placental which became aboreal in habit. Modes of aboreal life put a premium on movements of varied range and accurate adjustment of both limbs and body, also on sight. The evolving of a limb as a tool for uses additional to locomotion gives opportunity for limb and brain to interact. Physical opportunities beget mental opportunities, and conversely. Fruits picked, insects caught, will be handled and examined under combined touch, muscular sense and sight. The hand became a testing organ additional to and of greater range than the snout. Some lemur-like type arose, followed by some monkey-like type. The brains corresponding with these

are known and their increased scope of reaction and behaviour can be judged. Parts of the brain concerned with sight and manual dexterity increase greatly in transition from the lemurs up to the ape. The freeing of arm and hand from exclusively locomotor use and their employment for grasping and presenting objects to the eyes and mouth, along with correlative change of the visual axes to parallelism, greatly amplifying and enhancing stereoscopic vision, are thought to have been of great moment for advance toward the human stage of brain. A core of three-dimensional space neighbouring upon and centred at the animal then became visually, tactually and proprioceptively explorable by and familiar to experience on a scale of accuracy hitherto unapproached in animal life. Correlated with this is perhaps the curiosity characteristic of monkeys. The free hand itches to be employed. Later some form belonging to the ape-group, though not any existent ape, with anthropoid characters, came to live less in the trees and indeed far more on the ground, probably on the grasslands. With this went a greater attainment of the erect position, a more complete freeing of the arm and hand as a universal tool, and loftier point of vantage for the stereoscopic gaze. So an immediately sub-human and then, less than a half-million years ago, a human brain was reached.

**Had Man Had Wings.**—An inference from the above-traced course of evolution of the vertebrate brain is that the freeing of a limb-pair for more manifold use as a “tool,” while the other limb-pair still assured efficient land locomotion gave an impulsion or opportunity for cerebral development which was of decisive importance in the evolution of pallial growth and function. This inference raises the surmise that, had wings arisen in the vertebrates, as actually in the insect, without cost of a limb-pair to co-exist with “land-locomotor” leg and “tool” arm, the consequent additional experience and exploitation of a great three-dimensional medium (containing, unlike water, ample oxygen) would have evolved a brain of wider components and on fuller lines than is the human. A sobering reflexion is that should such a vertebrate form fraught with transcendent promise though it were, enter now upon evolution, man's dominance, leaving no part of the planet's surface untouched, would assuredly meet it and frustrate it by extermination, or by domestication. In the latter event its breeding would doubtless be controlled and guided to serve immediate human ends at the expense of the creature's own supreme ultimate possibilities. The evolutionary retrospect of the vertebrate brain shows clearly that the particular type of brain which thus far has by the development of intelligence done most to raise the level of life is not the later-launched avian brain but the earlier-launched mammalian. Subsequent to the start of that train of development which has accomplished the better brain were, however, not only earlier inferior types still proceeded with, but a partly fresh start was made on a type second-rate in itself and sterile of prospect—and indeed in performance through aeons of trial—as a possible new source for the first-rate. It would look as though after all the upward development of mind were not—at least in this planet—an object of the scheme of things.

**Lessons of Animal Behaviour.**—But to return to the observed relations between the pallium and mammalian behaviour, the classical observations of Lloyd Morgan showed that the newly-hatched chick pecks at things of all sorts as well as food, and that it learns to feed by profiting from the experience of the gustatory results of its random pecking. For this behaviour in the bird the striatum in absence of pallium suffices; it forms an instance of a modifiable behaviour in which one (a pleasurable) result stamps in the step which led to it, while another (an unpleasurable) result eradicates itself by stamping out an act which leads to it. Similarly, the dog, caught by too hot a morsel, fights shy of a next one. In the case of the dog more than *striatum* is at work; the pallium is necessary. Those who study the functions of the pallium look largely to animal behaviour as their key. The behaviour tests consist chiefly in training or learning of one kind or another. A simple form of maze with alternative paths, one leading to food another not; or one evoking an electric shock, the other not. Food which can be reached only by opening the tilt-latch or other fastening of a spring. Or the learning by experience that

some stimulus, *e.g.*, a sound signals the coming of food, or some other event with which in the animal's training it has been regularly associated. Such observations touch somewhat the same topics as do many of the anecdotes of sportsmen and animal-lovers. They have the difference, however, that laboratory observers control carefully the conditions surrounding an observation, simplify its factors, exclude extraneous variables, describe the resultant behaviour as objectively as possible, and arrange the experiments so as to permit quantitative statement.

In a good deal of this work it is now customary to apply the term reflex to the acts of the normal animal, *e.g.*, dog. Hitherto the application of the term reflex in physiology and in medicine has been to reactions, through the nervous system, which either in man are known to be, or in animals there is cogent reason to believe are, unaccompanied by mental experience. The extension of the term "reflex" to such an act on the part of one's dog as its coming when called by name may be taken to mean not that the observer denies that mental action attaches to the dog's behaviour, but that the observer explicitly disregards them, and is studying the behaviour solely as neuro-muscular bodily reaction, hoping thus to study the brain, much on the lines on which the spinal cord may be studied.

**Reflexes.**—All purely spinal and hind- and mid-brain reflexes of the placental mammal seem to be innate. They are transmitted by heredity and are the common property of the species, often of the genus. They include not only such simple acts as mastication, swallowing, the blink-reflex, the knee jerk, the scratch-reflex, crude sexual acts, etc., but standing, stepping, the falling cat's "righting" reflex, etc. They may develop only in adult maturity, but they are innate. Built up into chain-reflexes they make the basis of much instinctive behaviour.

Besides this type of reflex reaction the individual animal is able to develop other responses operating through its central nervous system. Thus, when the skin of one foot is subjected to a hurtful electric shock, retraction of the foot ensues. If along with or just preceding this, some other stimulus, *e.g.*, a sound, be given, then after a number of regular repetitions of this concurrence, the "sound" itself evokes the retraction of the foot. The response to such an associated stimulus is called an "associated" (Bechterew) or "conditioned" (Pavlov) or "individual" (Beritoff) reflex. The "associated reflex" is (dog) a response for which the neopallium is a *sine qua non*. In entire absence of the neopallium (cerebral cortex) the dog is incapable of acquiring any such responses and loses any such as it has already acquired. A dog's normal everyday behaviour is largely composed of such responses which the common happenings and experiences of its life as an individual from puppyhood onward have taught it. By loss of the pallium this stock of reactions is woefully reduced; it could not maintain even its base existence. Its behaviour is cut down to a few rigidly-fixed reactions. This is exemplified by Pavlov's decorticated dogs not able even to feed unless food were placed in the mouth; and by Dussier de Barenne's cats, although there one of them, in which the archipallium had been spared, still found its food by smell, and fed itself.

By means of the pallium any agent which acts on a receptor can by training become a signal evoking a particular movement or a secretion. The training required is that the agent act several times concurrently with the act of movement or secretion, or immediately before it, or, which is much less favourable, just after it (Beritoff). The movement or secretion to which the extraneous stimulus becomes attached as a signal is called the ground-act (Beritoff) or "unconditioned reflex" (Pavlov). In using the latter term it must be remembered that the protective movement in response to a hurtful stimulus which has for instance been much used as a ground-act, for which various neutral stimuli can, by training the individual, acquire the value of signals, is not itself entirely a reflex in the usual physiological sense of that term.

It is true that in the protective ground-act there is a kernel of reaction evocable even when only the spinal cord remains and therefore purely reflex. But to this in the protective act evoked by a similar stimulus in the intact animal there is much added. In this latter case cerebral and cortical reactions are superadded to

the strictly reflex. The ground-act is therefore a behaviour-response far more complex than that which is usually denoted physiologically a reflex. If we face the full biological situation it includes, instead of consisting merely of a pure physiological reflex, a large psychical reaction as well. It must, so to say, reverberate through wide regions of the pallium (cerebral cortex). Similarly, the secretion of the saliva in response to food in the mouth has been greatly used as a ground-act (Pavlov) and in terming it an unconditioned reflex we must remember that although secretion of saliva can after severe curtailment of the nervous system be obtained as a pure reflex, it yet, as obtained in the feeding response of the intact animal, is but one component of an immense reaction with emotional and other mental accompaniments, inevitably involving wide regions of the pallium. These ground-acts as reactions to the essential stimulus, *e.g.*, food in mouth for salivation, are innate inherited reactions, although possessing cortical extensions. The attaching them to other stimuli, by training in the individual, constitutes the so-called "conditioned reflex" of Pavlov, the "individually-acquired reflex" of Beritoff, and also involves the pallium. An individually-acquired reflex has been proved by the experiments of Pavlov to be in every case a response involving some part of the pallium. It is like the ground-act cortical, and it can be itself the ground-response for a further individually-acquired (*i.e.*, "conditioned") reflex, which latter again is of course cortical. This last is "secondary" by Pavlov, or by Beritoff the individually-acquired reflex of higher order.

At commencement of the acquiring of an individual reflex, the response tends to be evoked not only by exact repetition of the particular stimulus, but also by other stimuli broadly resembling it though not necessarily very closely. Anrep gives interesting figures of this. The individual reflex is said then to be in the generalized stage. Further training brings greater precision, in the sense that the response occurs only to more precise repetitions of the specific stimulus. This process is "differentiation." By this means it has been ascertained that the brain of the dog can discriminate between notes only one-eighth of a tone apart; and can hear notes of much higher pitch than the highest audible to man. It exhibits discrimination between figure patterns of relatively slight difference, *e.g.*, a thicker and a thinner capital T. It fails, however, to discriminate colours although well discriminating different luminosities.

The "individually-acquired reflex" is termed a "deferred reflex" when the beginning of the conditioned stimulus considerably precedes that of the ground-response, although continued until that of the ground-response has begun. The individual reflex so acquired brings its effect, *e.g.*, salivation, only after the conditioned stimulus has endured for a time practically corresponding with that employed in the repetitions giving the training. The name "trace-reflex" is given to individual reflexes in which the conditioned stimulus is allowed to lapse before the stimulus for the ground-response begins. The "trace-reflex" "differentiates" its stimulus relatively slowly and poorly; it is also less durable. It is noteworthy that although nociceptive stimuli have inborn defensive reflexes at command, such stimuli are difficult for induction of individual acquired reflexes—the training is long and uncertain, although sometimes successful (Pavlov). This suggests paucity of nociceptive afferent connections with the cortex in spite of probable wealth of connections with the thalamus.

If some unusual stimulus is employed concurrently with an established "conditioned" stimulus and in face of this concurrence the ground-stimulus is omitted, the individual acquired reflex occurs only weakly or not at all. The stronger this foreign stimulus the greater its inhibitory effect. This inhibitory result wears off under repetition of the same "foreign" stimulus. It has been shown in Pavlov's laboratory that the degree of inhibition exerted by the "foreign" stimulus is directly proportional to the intensity of the "investigatory reflex" which it excites. By "investigatory-reflex" (Beritoff's "orientation reflex"—the reaction agrees with Head's "vigilance"), is denoted an attitudinizing of the head which is excited by all sorts of stimuli but on repetition of the same stimulus rapidly tends to die out. It may accompany

various individual reflexes (Beritoff). It is destroyed by destruction of the pallium. It has been noted that incidental activity of a natural innate skin-reflex, *e.g.*, the scratch-reflex, may suffice to inhibit an acquired reflex belonging to quite another distant skin-region, *e.g.*, of forefoot (Beritoff).

**Experimental Investigations.**—The effect of variously-situate partial destructions of the cerebral cortex upon acquired reflexes has been studied (Pavlov). The destruction of no one single even large field of cortex precludes totally or permanently all acquisition of "individual reflexes." Pavlov regards this as conclusive against the teaching that one special field for "association" exists in the cortex. The extirpation of a part of the cortex of whatever region temporarily upsets the "conditioned" reflexes, and with selective disturbance of them. After bilateral extirpation of the occipital region (visual) the dog never again directs its movements by sight, and fails to distinguish size and distance of objects. Full and bilateral destruction of this region in man causes total blindness; but the dog after bilateral extirpation of even much additional to both occipital regions still discriminates light from dark, and good "conditioned" reflexes were acquired with light difference as stimulus. Bilateral extirpation of the temporal lobes (acoustic) precluded acquired reflexes to sounds, but only for a time; conditioned reflexes to single sounds and even with some discrimination of tone-sequences could later be established. Yet after loss of the temporal lobes the dogs, and many observers have found it so, ceased permanently to respond to their names. Bilateral destruction of the parietal and "motor-area" regions, especially impaired "acquired reflexes" trained on touch and proprioception respectively, and especially in the limbs. After bilateral removal of the frontal lobes formerly-acquired visual and auditory "conditioned reflexes" returned and new ones could be established soon after the operation (Babkin). There ensued a persistent supersensitivity of the skin.

In sum, localized damage to cortical areas affects "acquired" reflexes selectively according to the species of receptor of their stimulus (psychologically, their sense-modality) and to the topographical seat of the lesion in the field of the cortex. Pavlov concludes that the motor area of the cortex is merely the area of proprioceptive receptors. He denies to the cortex any special association area. "The cerebral cortex should be regarded as the essential organ for the maintenance and establishment of conditioned reflexes." It may be added, on the basis of older experiments, that total destruction of the pallium of only one hemisphere in the dog impairs its behaviour relatively little.

Instinctive behaviour has been defined (Lloyd-Morgan) as "that which is, on its first occurrence (in the individual) independent of prior experience; which tends to the well-being of the individual and the preservation of the race; which is similarly performed by all the members of the same more or less restricted group of animals, and which may be subject to subsequent modification under guidance of experience." It is an innate behaviour-trend which a certain more or less complex group of stimuli of external and internal origin can call forth.

The experiments of Ceni show that while in the heap the train of behaviour corresponding with incubatory and maternal rearing of the young is not obviously disturbed by destruction of the whole pallium, in the bitch on the contrary not only does destruction of the pallium *in toto* cause all maternal instinctive behaviour to disappear, but that bilateral destruction even confined to the frontal region does so. Inherited behaviour as well as individual acquired behaviour is therefore laid up in the cerebral cortex of the dog.

With those on the dog may be compared observations on the rat (Lashley) in regard to ability to learn and retention of learnt behaviour *e.g.*, for a maze or the entrance-fastening to a food box, and the effect upon them of pallial destructions. With learning of a simple maze acquisition occurs at normal rate after bilateral destruction of any one-third of the cortex, and similarly is retained. With a test in which two alleys to food are offered, one lit the other dark, the food being attainable always by the lit, never by the dark one, bilateral destruction of the occipital third (visual) of the pallium abrogates totally the successful behaviour

already learned, but offers no impediment to acquiring it as quickly as in the original training. With a more complex test for entrance to a food-box the learnt solution of it and its reacquisition is disturbed, but not completely abolished, by bilateral destruction of either the frontal or occipital regions.

Turning from mammals lower than the dog to others higher, the older experiments on the monkey, while showing greater impairment of motor behaviour than in the dog, gave evidence of considerable powers of recuperation. In monkeys, the destruction of the precentral gyrus "the motor area" (perhaps proprioceptive) of both hemispheres, the animals having previously been trained in habits of manipulation, revealed on subsidence of the temporary paralysis perfect retention of these habits (Lashley). Nor did even the paralysis recur on destruction of the striatum subsequent to recovery from the diplegia. Even in the man-like apes the temporary arm-paralysis caused by destruction of the cortical "excitable" area for the arm produces no permanent impairment of individually-acquired motor habits executable by that arm. The peeling and other manipulations in eating a banana, the taking and holding of a cup of water to drink from (Graham Brown and Sherrington), the learnt "hand-shake" with a visitor (Leyton and Sherrington) are all recovered. Further, the recovery is not frustrated or undone by additional removal of the arm area of the opposite hemisphere or of the post-central gyrus of the same side.

But these are relatively restricted lesions and in the man-like apes, as in man, objective study solely by means of motor-behaviour apart from speech of the effects of damage to this or that field of neopallium (cerebral cortex) becomes less and less adequate to the complexity of the phenomena if all reference to psychical accompaniment be eschewed. The fully developed pallium is mainly so to say a mental organ. To a spectator otherwise unacquainted with the play, "Hamlet" in dumb-show would convey but meagrely that play's contents. The experiments of Thorndike and others go to show that lower mammals give little evidence for their possession of images in the form of ideas; or in their learning of mazes, door-fastenings, etc., of doing so even by imitation. There is, it is found, some power of imitation, though not so much as has been generally supposed, in monkeys; and a questionable existence of image-ideas. A situation before which a cat is helpless a monkey will grasp. A chimpanzee will solve a situation by making use of some object present at hand as an implement; will recall the position of an object it has seen placed in hiding a day previous; will in some cases fetch an object, remembered though out of sight, to serve as implement suitable for solving a newly-arisen situation (Verkes); and has been observed to pause in a waiting attitude trying, as it were, to "see" how to attain indirectly an objective unattainable directly, somewhat as a man "stops to think." It is inferred that the man-like apes form and retain memory-images not essentially dissimilar from man's memory-images.

It would seem that no gross lesion of the neopallium occurs without inflicting a certain degree of lasting disturbance upon mental reactions. It may be that that impairment will, by improved analysis of the conditions, be found to be essentially of the same kind for all regions of the pallium. Be that as it may, it is already certain that disturbances predominantly in this or that sphere of sense are related regularly to spatially separate areas of the human cortex; and that impairment of the performance of "willed" movements by the muscles, especially of limbs and face in the opposite side, results from damage of a particular pallial region, the pre-central gyrus in man just as in the ape, and more severely. Speech *per se* without any paralysis of the motor mechanisms of its production is affected very commonly by injury of the cerebral cortex. The manner and degree of the disturbance of speech so produced differs greatly in differently placed structural lesions. Their study, although difficult, affords perhaps the best opportunity for analytic examination of the mental functions attaching to the neopallium in man. They form a theme too large and also too special to be entered upon adequately here.

**The "Motor" Cortex.**—Electrical stimulation, so useful a physiological agent in the case of nerve-trunks and many of the nerve-centres, fails in its application to most parts of the surface of

the pallium, especially in the higher animal forms. From certain, however, of the areas of the cortex it does, and especially in the highest forms, evoke motor responses with regularity. The main such area occupies in ape and man the "pre-central convolution" and is called the motor area. The movements evoked occur in the crossed half of the body. The particular muscular field yielding the motor response differs for different parts of this area, and for each such part is fairly constant. Thus flexion of the arm will be excitable from one set of points, and extension of the arm from another set; opening of the jaw from one set; movement of the tongue from another, and so on. The topography of the representation of the different parts of the body is shown in fig. 17.

One character of these movements is that they tend to spread. Thus when the point for the thumb is stimulated the movement will begin in the thumb, then under continuance of the stimulus, may spread to the fingers, then to the wrist, the elbow and shoulder, and even to the face and leg as well, so that the musculature of all one side of the body may thus be simultaneously convulsed. This spread is called the "march," because it resembles a feature, termed by Hughlings Jackson, the "march," in the epileptic seizure. Strong and prolonged stimulation of a "motor cortical" point is apt to be followed by a clonic (convulsive) spasm resembling that of the true epileptic seizure. The representation of certain fields of the musculature of the body is more liberal than that of others. Variety of movement rather than power of movement seems to demand extent of cortex. The cortical area for the thumb (gorilla and chimpanzee) is larger than those for the whole of the abdomen and chest combined. The cortical area for the tongue (anthropoids) is larger than that for the whole of the neck. Only in very few cases is the movement bilateral, *i.e.*, both right and left, from unilateral cortical stimulation. One of these rare instances is that of the vocal cords which bilaterally adduct (phonation). Another is that of the eyelids, which blink for both eyes. A condition for obtaining the motor responses from this "motor" field of the pallium is that the narcosis under which the animal is necessarily placed at the time of experimenting must not be too heavy. It is known from observations in man by the surgeon (Harvey Cushing and others) that no pain or indeed other sensation attaches to electric stimulation of the "motor cortex." All that is felt, even in the fully conscious person, is some perception of the movement which is evoked. If the narcosis go beyond inducing sleep of a natural depth, no visible response to stimulation, however strong, is obtainable from the pallium, although spinal reflexes, *e.g.*, the knee jerk, are still readily elicitable by their appropriate stimuli.

It was at one time thought that the response on application of electrical currents to this cerebral surface was due to stimulation, not of the cortex itself, but of bundles of nerve-fibres under the cortex. The distinction if existent would not be of much significance, because such fibres must issue from the cortex; that it is, however, some element in the cortex itself which is excited may be regarded as established. Probably the element in question is the large nerve-cell, of which numbers are scattered throughout this excitable field. Each such large cell sends a long thread-like fibre down far beyond the confines of the forebrain itself. These cells get severally into touch with the primary motor nerve-cells in the various segments of the head and body. They form together a direct path from motor cortex to the spinal cord, etc., the *pyramidal tract*.

When this excitable field of the cortex was first investigated it was thought by some that it might prove to be as the immediate starting-place of a path executive of "willed" cuts of movement. The immediate and severe paralysis of "willed" movement, which, in man and the monkey, results from destruction of this excitable field of cortex, supported such a view. But there follows in course of no long time a remarkable "restitution" of the "willed" movements, even in the man-like apes. And this is not due to vicarious functions on the part of the corresponding area of the opposite half of the pallium (Graham Brown and Sherrington) or of the underlying striatum (Lashley). The inference is that other fields of cortex than the so-called motor and other routes than the pyramidal tract are capable of carrying out willed acts.

That the movements excited from the "motor cortex" are produced via the fibres of the pyramidal tract seems clear; they are precluded by severance of that tract below the cortex. But that they resemble truly closely "willed" acts of movement is unlikely on several grounds: (1) Severance of the afferent spinal roots supplying a limb although it does not impair the motor supply of the muscles, etc., in the least, disturbs the willed movements of the limb, very greatly indeed, rendering them so inaccurate and wild as to be worse than useless. The animal, *e.g.*, monkey, soon relinquishes use of the "deafferented" limb altogether. Electrical stimulation of the field of the motor cortex corresponding with the deafferented limb nevertheless evokes in it all the movements normally so elicitable, and with no detected departure from the normal. The willed movements are grossly disturbed; yet the motor responses of the "motor" cortex remains practically unaffected. (2) Degeneration experiments show that the spinal terminals of the fibres (pyramidal tract) from the motor cortex are scattered actually among the ultimate motor cells themselves. The motor cortex presumably, therefore, makes direct synaptic junction with the final motor cell which directly innervates the muscle. This simplicity of connection of the "motor" cortex with the muscle could hardly provide for the complexity of a "willed" movement. But it accords with the further fact that under stimulation of the "motor" cortex the rate of rhythm of response of the muscle follows the rhythmic stimulation of the cortex *pari passu* even up to 180 per sec. (Cooper and Denny-Brown). Also the time interval between delivery of the electrical stimulus to the motor cortex and the response by the muscle is only 130, which is less than the latent period for many spinal reflexes (Cooper and Denny-Brown). (3) Recent observations indicate that the electrical and myographic behaviour of the muscles under motor-cortex stimulation denotes conflict of excitatory with inhibitory influence, simultaneously exerted on the same muscle. The clonic after-action so characteristic of motor-cortex excitation seems traceable to alternating excitation and inhibition (Cooper and Denny-Brown). All this renders it unlikely that the "motor" cortex and the pyramidal tract descending from it to play upon the motor nerve-cells yield of themselves, at least when excited artificially (*i.e.*, electrically in experiment) movements truly resembling "willed" movements.

Two patients offered opportunity while in a fully conscious state for elicitation of movements of the right hand by electrical stimulation of the motor cortex (Cushing). As reported from their own introspection the reaction was attended by no sensation other than a secondary awareness of changed position of hand and fingers. With the anthropoid ape an impressive observation repeatedly noted is the seeming entire ignorance on the part of the animal, on its awakening from a "motor cortex" ablation experiment, of any disability precluding its performance of its willed acts as usual. Surprise at the failure of the limb to execute what it intended seemed indubitably the animal's mental attitude, and not merely for the first few minutes but for many hours. The animal was slow to realize the limb's inability. It was often many hours before repeated and various failures to execute ordinary acts for climbing, feeding, satisfying its curiosity, etc., gradually impressed upon the animal that the usual services were no longer to be expected from the limb. Even after this lesson seemed to have been learnt an emergency would call forth a new attempt and surprise at failure as though the former experience has been for the moment again forgotten. The impression conveyed is that the fore-running idea of the act intended is present and as definitely and promptly developed as usual. The surprise seems to argue unfulfilled expectation, and defect in the motor execution rather than in the mental execution of the act, raising the question whether the function of the part of the cortex ("motor") ablated in such cases be not indeed infra-mental.

### ANATOMY OF THE BRAIN

The brain is that part of the central nervous system which is contained within the skull. It is the seat of consciousness and

memory and it contains the receptive centres for various sensory impulses which come from the skin, joints, muscles and organs of special sense. It has the power of originating movements and also of controlling and co-ordinating the action of muscles which are primarily innervated by nerve cells in the spinal cord and lower centres of the brain itself. Further it has the faculty of correlating the knowledge acquired by experiences, and of utilizing the deductions thus obtained for synthetic mental processes.

**General Structure.**—It consists of an upper main part, the *cerebrum*, and a hinder small part, the *cerebellum* (figs. 7 and 4). The lowest part of the brain, the medulla oblongata, is continuous through the foramen magnum with the spinal cord. The brain and spinal cord constitute the *central nervous system*, whereas the nerves passing to and from the central nervous system form the *peripheral cerebro-spinal system*. The nervous system also in-

The floor of the 4th ventricle, or fluid-containing cavity communicating with the spinal cord, is seen from behind. Note the origins of the 4th cranial nerves and the corpora quadrigemina

cludes certain nerve-centres and nerve-fibres which, without our conscious knowledge of the processes concerned, control the vital functions of the body, such as the circulation of the blood and respiration. This system, since it acts to a large extent independently of the will, has been termed the *autonomic system*. It includes the sympathetic and parasympathetic systems. Through communicating branches the brain is capable of influencing organs which are supplied by the autonomic system, e.g., the salivary glands and heart, both of which may be acted on by fear. Under ordinary circumstances, however, the functions of the internal organs are carried out in a reflex manner, and without the individual being conscious of the processes involved.

The brain is invested by three membranes. If the membranes are removed its surface is seen to be moist and of a greyish-white colour. It is characterized by sinuous foldings of the superficial stratum or cortex. These are the gyri or convolutions, and they are separated by grooves or sulci. The main part of the brain is sub-divided by a deep longitudinal fissure into right and left hemispheres. The hemispheres are connected by transverse bands of nerve fibres called commissures. The largest of these crosses the middle of the great longitudinal fissure and is called the corpus callosum (fig. 4). In addition to the hemispheres and cerebellum, the brain comprises the inter-brain or thalamencephalon, the midbrain or mesencephalon, the pons Varolii, which forms a transverse bridge between the two cerebellar hemispheres, and finally the medulla oblongata, which is situated below the pons and cerebellum and connects these with the spinal cord.

**Membranes of the Brain.**—These are an outer, tough, fibrous layer, the *dura mater*; a thin, intermediate, web-like tissue, the *arachnoid mater*, and a soft, vascular inner covering, the *pia mater*.

The *dura mater* (fig. 1), lines the cranial cavity. On its outer surface are meningeal arteries and veins which serve for the nutrition of the bone. If torn in an injury to the skull an effusion of blood occurs between the *dura mater* and the bone, which, by

exerting pressure on the underlying brain, causes paralysis of the opposite side of the body. The inner surface of the membrane which is in relation with the brain is smooth and moist. The dura mater also forms partitions between the hemispheres of the brain and cerebellum. These septa (fig. 1) are folds of the dura mater and consist of two layers, blended where they touch but separated along the attached borders of the septa to form venous channels

FIG. 3.—HORIZONTAL SECTION THROUGH THE LEFT HALF OF THE MEDULLA OBLONGATA

The section traverses the inferior olivary nucleus which connects with the opposite cerebellar hemisphere and shows the positions of the gracile and cuneate nuclei, where the sensory impulses coming from the spinal cord end and the superficial arcuate fibres take origin

or sinuses, by which blood and also excess of cerebrospinal fluid is drained from the brain into the great veins of the neck which carry it back towards the heart.

The secretion from the pituitary gland (fig. 4) is also carried away into the general blood stream by small venules, which open into the neighboring cavernous and intercavernous venous sinuses (fig. 1). Absorption of the cerebrospinal fluid is carried out, to a large extent, by small villous processes of the arachnoid membrane which project into the venous sinuses and spaces of the dura mater, and are most numerous in the neighbourhood of the sagittal sinus (fig. 1). If this absorption is prevented or retarded the intracranial pressure of the cerebrospinal fluid rises, and one form of hydrocephalus (*q.v.*) results. In old age the arachnoid villi enlarge to form Pacchionian bodies. Between the dura mater and the subjacent arachnoid membrane is an interval called the subdural space. It contains a small quantity of fluid which serves to lubricate the smooth inner surface of the dura mater.

Beneath the dura mater is the arachnoid membrane, which is separated from the pia mater by an interval—the subarachnoid space. This is traversed by a network of delicate fibrous bands. The meshes of this network are filled by the subarachnoid cerebrospinal fluid, while the larger thin-walled cerebral arteries and veins covering the surface of the brain lie in the thin bands of fibrous tissue forming the net.

The pia mater is the delicate vascular membrane which forms the immediate investment of the brain and dips down into the fissures between the convolutions. It contains the smaller arterioles and venules which supply the subjacent cortex of the brain. A large triangular fold of pia mater (velum interpositum) is included in the great transverse fissure lying between the corpus callosum and fornix above, and the roof of the third ventricle and optic thalami below (fig. 4). This pyramidal fold contains the two great cerebral veins of Galen, which drain the blood from the

interior of the brain. Vascular fringes at the margin of the fold project into the lateral ventricles, and similar fringes project from the under surface of the fold into the third ventricle. These fringes are the choroid plexuses of the lateral and third ventricles, and a similar choroid plexus is found in the roof of the fourth ventricle. They are covered by a secretory layer, called the choroidal epithelium, whose function is to secrete the cerebrospinal fluid.

In the lower part of the roof of the fourth ventricle are three openings, a median, the foramen of Magendie and two lateral, the foramina of Luschka. These form a communication between the cerebrospinal fluid in the ventricles of the brain and that contained in the subarachnoid space. Obliteration of these openings by meningitis produces an obstructive hydrocephalus, in which the accumulation of fluid is entirely intraventricular.

**Ventricles.**—These are cavities containing fluid situated in the substance of the brain and lined by a thin membrane, the ependyma. The true ventricles are four in number, namely, the right and left lateral ventricles, which are contained in the cerebral hemispheres; the third ventricle, situated between the optic thalami, and the fourth ventricle in the hind brain. Each lateral ventricle is connected with the third ventricle by a small opening, the interventricular foramen of Monro; and the third ventricle is joined to the fourth by a narrow channel, the aqueduct of Sylvius (fig. 4). The fourth ventricle communicates below with the central canal of the spinal cord and with the subarachnoid space by the foramina of Magendie and Luschka.

The cerebrospinal fluid, which is contained in the ventricles and subarachnoid space, acts as a mechanical support to the brain and spinal cord; it also takes the part of the tissue-fluid and lymph found in other parts of the body. (See NEUROPATHOLOGY.)

**Medulla Oblongata.**—This is situated in the lower and posterior part of the cranial cavity. It appears to be a direct continuation upwards of the spinal cord, but differs from this in the arrangement of the fibres composing the nerve tracts and in the disposition of the grey matter. It contains the important vital

The section traverses the corpus callosum, the medulla oblongata, lowest part of the brain, and the pons varolii, which connects the cerebrum and cerebellum. The 3rd and 4th ventricles are exposed with their connecting aqueduct of Sylvius; also the communication of the 3rd with the lateral ventricle by the interventricular foramen of Monro

centres known as the cardiac, vasomotor and respiratory centres. These are situated in the lower part of the floor of the fourth ventricle (fig. 2). Longitudinal bundles of nerve fibres connect the medulla oblongata with the pons Varolii, and two diverging bundles of fibres called restiform bodies join it to the cerebellum.

FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY"

FIG. 5.—DIAGRAM SHOWING THE ARRANGEMENT AND CONNECTIONS OF THE NERVE CELLS AND NERVE FIBRES OF THE CEREBELLAR CORTEX

The principal longitudinal tracts which connect the pons with the medulla on each side are (1) the pyramidal tract, (2) the posterior or median longitudinal bundle, and (3) the median lemniscus or fillet.

(1) The pyramidal tracts consist of motor fibres each of which descend from the motor area of the cerebral cortex through the internal capsule, midbrain and pons to the anterior part of the medulla (figs. 9 and 3). Here they form two parallel strands, one on each side of a median vertical groove. In the lower part of the medulla oblongata the greater number of the fibres of the pyramidal tract cross over to the opposite side of the spinal cord, where they form a bundle of descending fibres called the crossed pyramidal tract. The remaining fibres are continued downwards on the same side of the cord as the direct pyramidal tract. Eventually these fibres also cross to the opposite side. (*See SPINAL CORD.*) The crossing of the motor nerve fibres in the medulla oblongata is called the decussation of the pyramids; and since, with few exceptions, all motor fibres, and also sensory fibres, cross to the opposite side, each cerebral hemisphere dominates the muscles of and receives sensory impulses from the opposite side of the body.

(2) The median longitudinal bundles are paired tracts of nerve fibres, which connect the nuclei of origin of certain cranial nerves, on the same side of the brain, with one another, and also by means of decussating fibres with nuclei on the opposite side. Each bundle extends from the midbrain, through the pons Varolii to the lower part of the medulla oblongata. By means of these tracts the nuclei of origin of certain nerves controlling bi-lateral movements are correlated, *e.g.*, the muscle which draws the left eye towards the median plane will act in harmony with the muscle which draws the right eye away from the median plane.

(3) Each median fillet (fig. 4) is a longitudinal tract of ascending sensory fibres lying close to the median plane, between the pyramidal tract and the median longitudinal bundle. The fibres of the right and left tracts cross the median plane, forming the sensory decussation. This lies above the level of the motor or pyramidal decussation. The median fillets thus carry the sensory fibres coming from one side of the body to the central ganglia of the opposite cerebral hemisphere.

The sensory impulses coming from the spinal cord end in cell-stations in the medulla, the gracile and cuneate nuclei (fig. 3). It is from these that the superficial arcuate fibres, which pass to the cerebellum, and deep arcuate fibres (median fillet) take origin.

The latter thus form one link or relay in the main sensory tract to the cortex. Immediately external to the pyramidal tract on the anterior aspect of the medulla is an oval swelling, the olive (fig. 9), and external to this the inferior peduncle of the cerebellum, or restiform body. The olive lies over a folded lamina of grey matter in the substance of the medulla (fig. 3); this is the inferior olive. It is connected with the opposite cerebellar hemisphere by fibres which cross the middle line and reach the cerebellum by means of the restiform body. The superficial origin of the lower cranial nerves from the 6th to the 12th is shown in fig. 9; the nuclei from which the motor fibres originate and those in which the sensory fibres terminate lie in the substance of the medulla and pons. Like the spinal nerves they are connected by tracts of nerve fibres with the opposite cerebral hemisphere.

**Pons Varolii.**—This (figs. 4 and 9) lies between the medulla oblongata and midbrain and forms a bridge which connects the two cerebellar hemispheres. It forms, by its posterior surface, the upper half of the floor of the fourth ventricle (fig. 2). It contains the nuclei of origin or termination, of the fifth, sixth, seventh and eighth cranial nerves. A conspicuous band of transverse fibres lies superficially and crosses beneath or ventral to the pyramidal fibres, which pass through the pons from the internal capsule and midbrain to the medulla oblongata. Some of the transverse fibres, however, lie more deeply and intersect the longitudinal fibres of the pyramidal tract. Most of the transverse fibres arise from nuclei of the pons which are connected with the cortex of the frontal and temporal lobes of the cerebrum on the same side, and crossing the midline eventually reach the cortex of the opposite cerebellar hemisphere. The most important longitudinal tracts of nerve fibres traversing the pons are the pyramidal tracts, the longitudinal bundles, and the ascending sensory fibres of the median and lateral fillets. The lateral fillet is the main auditory tract which, arising from the terminal nuclei of the cochlear nerve of the ear, ascends to the midbrain and internal geniculate body.

**The Cerebellum** consists of a central part, the vermis, and two lateral hemispheres. Each hemisphere is connected with the brain stem by three peduncles: (1) the inferior or restiform body of the medulla; (2) the middle or brachium pontis; (3) the superior or brachium conjunctivum. The last-named joins the cerebellum to the midbrain and conveys efferent fibres, leaving the cerebellum and ascending to the important red nucleus in the opposite side of the midbrain (fig. 6).

The cerebellum correlates sensory impulses from the internal ear, and also from muscles and other organs. These efferent impulses which reach the grey matter of the cortex of the cerebellum are believed to pass thence to the dentate nucleus, a convoluted lamina of grey matter situated in the substance of each cerebellar hemisphere. From this a relay of fibres ascends to the opposite red nucleus (*see* below for Midbrain). The superficial surface of the cerebellum differs from that of the cerebral hemispheres. In place of convolutions, the vermis and hemispheres of the cerebellum are crossed by numerous transverse fissures, which mark off a series of folds or folia. The general arrangement of these is seen in a median section through the vermis, which presents a branched appearance called the *arbor vitae*. The surface of the cerebellar hemispheres and central lobe is subdivided into lobes and lobules by deep fissures, a full description of which must be sought in textbooks of anatomy.

**Microscopical Structure of the Cerebellum.**—The cortex of the cerebellum consists of a superficial stratum, the molecular layer, an intermediate layer which contains the cell-bodies of branched Purkinje cells (fig. 5), and an inner deep stratum, the granular layer which rests upon the central white matter. The latter is formed by medullated nerve-fibres which course to and from the grey matter. The Purkinje cells are remarkable for their large size and extensive connections. The cell-bodies are pear-shaped and arranged in a single layer. From the outer end of each cell, processes arise which branch out in the molecular layer.

These processes are the dendrites, and the branching takes place chiefly in a plane at right angles to the longitudinal axis of the folium in which it lies. The dendrites of the Purkinje cells are intersected at right angles by parallel fibres which run in the direction of the folium. These fibres are derived from axons of the granule cells in the inner stratum of the cortex, which pass outwards and divide in the molecular layer in a T-shaped manner, into right and left branches. The bodies of the Purkinje cells are, moreover, surrounded by a network of fibres which originate from "basket" cells in the molecular stratum; and their branches are also accompanied by delicate tendril or climbing fibres, which are efferent nerve fibres from the white matter.

Although areas of the cerebellar cortex cannot be mapped out by response of particular groups of muscles to electrical stimulation, it is possible on morphological grounds, by means of experimental work and by the tracing of tracts of nerve fibres entering the cerebellum, to locate areas of the cortex according to the fibres which they receive from particular parts. Thus it is generally admitted that the head and neck are represented in the anterior part of the vermis, the trunk in the posterior part, and the limbs in the apical region of the vermis and hemispheres. References to literature on cerebellar localization will be found in C. J. Herrick, *An Introduction to Neurology* (1927) and H. Woollard, *Recent Advances in Anatomy* (1927).

**The Midbrain** (mesencephalon) connects the parts below the tentorium cerebelli (fig. 1) with the cerebral hemispheres above the tentorium. It is traversed by the aqueduct of Sylvius (figs. 4 and 6). The part which lies above the aqueduct, called the roof plate or tectum, is subdivided by a crucial sulcus into four rounded swellings. These are the colliculi or corpora quadrigemina. The upper pair of these bodies receives nerve fibres from the retina, which reach them through the optic tracts. They are concerned in the regulation of the movements of the eye and in the pupillary reflexes. The lower pair serves as a cell station in the path of the auditory impulses which pass from the cochlea to the cortex of the temporal lobe. The grey matter in the roof of the aqueduct receives an important tract of nerve fibres from the spinal cord, known as the spino-tectal.

A similar bundle, the spino-thalamic tract, also traverses the midbrain. Both tracts convey the more primitive sensations of pain, heat and cold to the receptive centres in the brain. These have been described by Head as protopathic sensations, to distinguish them from the finer and more recently evolved sensations of touch, which he terms epicritic. The latter ascend in the posterior columns of the spinal cord to the gracile and cuneate nuclei

(fig. 3). From these a relay of nerve fibres ascends through the medulla oblongata, and crossing in this to the opposite side of the brain, passes as the median fillet through the pons and mid-brain to the thalamus of the brain. From the optic thalamus another relay of fibres carries the sensory impulses to the cortex of the brain. These fibres diverge as they traverse the white matter of the brain, thus forming part of the corona radiata.

The part of the midbrain which lies ventral to or below the aqueduct forms the *crura cerebri*. These are two diverging limbs

FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY"

FIG. 6.—TRANSVERSE SECTION THROUGH THE MIDBRAIN, SHOWING THE LEFT HALF OF THE UPPER PART. THE MOTOR FIBRES OF THE PYRAMIDAL TRACT COURSE DOWNWARDS IN THE CENTRAL PART OF THE CRUSTA

which ascend from the pons Varolii to the right and left cerebral hemispheres (fig. 9). The superficial part (crusta) of each crus, (fig. 6), consists of motor and sensory nerve fibres. The former constitute a part of the great pyramidal tract which descends from the motor area of the cerebral cortex to the opposite side of the spinal cord. The sensory fibres pass from the frontal and temporal lobes to the pons, and thence to the opposite side of the cerebellum. Behind, or dorsal to the crusta, is a lamina of pigmented nerve cells (substantia nigra) which separates the crusta of one side from the corresponding side of the tegmentum. The latter consists of two symmetrical halves, connected by a median raphé. This is traversed by decussating fibres, the greater number being the cerebellar fibres already mentioned as issuing from the dentate nucleus, travelling by the superior peduncle to the midbrain, and then crossing to the red nucleus of the opposite side (fig. 6).

From this important nucleus a tract of nerve fibres descends to the spinal cord, where it forms connections with the motor cells in the grey matter of the anterior cornua. (*See SPINAL CORD.*) This is the rubro-spinal tract of Monakow. The red nucleus is also connected with the central ganglia of the brain. By means of these connections, it is believed that the cerebral hemispheres control, through the red nucleus and rubrospinal tract, the more reflex movements carried out by the spinal cord, such as balancing movements and the maintenance of posture. If this controlling influence is interrupted, for instance by an injury to the mid-brain, involving the red nucleus, rigidity, known as decerebrate rigidity, arises from overaction of the muscles. It disappears from any particular group of muscles if the sensory roots of the nerves coming from the corresponding area are divided.

In the tegmental part of the midbrain are also situated the longitudinal association tracts, known as the anterior and posterior longitudinal bundles; and the fountain decussation of Meynert, which connects nuclei in the superior quadrigeminal body of one side with the nuclei of cranial nerves of the opposite side of the

brain; finally, the midbrain contains the nuclei and roots of origin of the third, fourth and part of the fifth cranial nerves, in the grey matter surrounding the aqueduct of Sylvius. (See NERVE.)

**Cerebral Hemispheres.**—One of the most distinctive features of the human brain is the large size of the hemispheres and the high degree of specialization in the microscopical structure of the cortex. The surface of each hemisphere is, for descriptive purposes, subdivided into lobes and lobules. Certain fissures and lines which are arbitrarily drawn between these are employed for demarcating the boundaries of these areas. The names of the principal fissures and lobes are indicated in figs. 7 and 8, and it will only be necessary to draw attention to certain of the more important. Thus the central fissure, or fissure of Rolando, is situated on the superficial surface and separates the frontal from the parietal lobe. The lateral fissure or fissure of Sylvius marks off the temporal lobe from the parietal and frontal lobes. On the median surface (fig. 8) are the calloso-marginal, the parieto-occipital and calcarine fissures, which limit the frontal, limbic, parietal and occipital lobes.

The central fissure marks the posterior limit of the important motor area of the cortex (fig. 17). Electrical stimulation of particular parts of this area produces definite movements of groups of muscles, the action of which is normally initiated and controlled

hearing (fig. 7). The auditory area of the brain receives sensory impulses by way of the auditory radiation from the inferior corpus quadrigeminum and internal geniculate body of the same side. These, the lower auditory centres, are connected with the opposite ear by means of the lateral fillet.

The front part of the hippocampal gyrus, with its hook-like end, the uncus, is the higher cortical centre for the sense of smell.

FIG. 7.—LATERAL ASPECT OF RIGHT CEREBRAL HEMISPHERE SHOWING THE FISSURES OF SULCI, AND THE BASILAR, TRIANGULAR, AND ORBITAL PARTS OF THE INFERIOR FRONTAL GYRUS

by the part stimulated. Injury to the same part causes paralysis of the corresponding muscles. The cortex of the occipital lobe which surrounds the posterior part of the calcarine fissure is the visuo-sensory area for reception of visual impulses from the retina. The visuo-sensory area is surrounded by a marginal zone which extends on to the outer aspect of the occipital lobe, termed the visuo-psychic area. (See VISION.)

The middle part of the first temporal gyrus and the adjacent gyri on the lower lip of the fissure of Sylvius are concerned with

This is the most primitive of the special senses. It is closely associated with the sense of taste, and is both relatively and absolutely more highly developed in lower types of vertebrate animals than in man (figs. 8 and 16). That part of the brain which is concerned in the sense of smell is called the rhinencephalon. In addition to these, there is a large area behind the central fissure which extends forwards on to the motor area. This is the cutaneous sensory, or tactile area (fig. 16, D).

The areas of cerebral cortex lying between the special and cutaneous sensory areas are believed to function as association centres between the different senses, and as centres in which the memory of associated sensations is stored. The prefrontal region, which is more highly evolved in man than in any other animal, is connected by association fibres with all the various sensory and motor areas, and more especially with that part of the adjacent motor area which is concerned with the movements of the eyes. It is therefore believed that this part of the cortex may control skilled movements which are dependent on impulses reaching the brain from the eyes, and which require close attention and a knowledge or memory of past experiences. For instance, such movements as those of the lips and tongue, or of the hand, which have given man the powers of speech and of writing. If the upper and lower lips of the fissure of Sylvius (figs. 7 and 10) are separated a triangular area of submerged cortex will be exposed. This is the island of Reil, or Insula. It lies over the outer aspect of the corpus striatum, and the lips of the fissure which overlap it are called the opercula insulae. In the human foetal brain, and the brains of most animals, this area of the cortex is exposed on the surface.

The basal ganglia are three masses of grey matter embedded in the cerebral hemispheres (fig. 10). The basal ganglia consist of the optic thalami, the caudate and lenticular nuclei. The optic thalamus is a receptive centre for primary sensory impulses, and an important cell station in the path of sensory fibres to the cerebral cortex. The caudate and lenticular nucleus, with the white matter which surrounds the lenticular nucleus, form the corpus striatum. The white fibres lying to the inner side of the lenticular nucleus are called the internal capsule, those to its outer side form the external capsule. The former consists of sensory fibres passing to the cortex, motor fibres of the pyramidal tract passing from it, and association fibres passing between the nuclei.

**The Cerebral Cortex** is the stratum of grey matter which covers the central white matter of the hemispheres. It consists of nerve cells, nerve fibres, and a supporting tissue—the neuroglia.

FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY"

FIG. 9.—DIAGRAM OF THE BASE OF THE BRAIN, INDICATING POSITION OF THE IMPORTANT NERVES AND PARTS

It exhibits a definite stratification into layers of nerve cells and nerve fibres. In sections of the fresh brain, the main strata are easily recognizable by the unaided eye, and more especially so in the visual cortex, or area striata. Various zones may be distinguished in this way, and it is found that the naked eye appearances correspond closely with the finer details revealed by microscopic preparations. A general idea of the disposition and appearance of the cell elements and nerve fibres will be gained by reference to fig. 11, in which isolated cells are depicted on the left and the fibre systems on the right.

It will be noted that the superficial lamina, or outer fibre layer, is largely composed of nerve fibres running tangentially or parallel with the surface. Many of these fibres are branches of the peripheral processes of small and large pyramidal cells contained in the subjacent strata of the cortex; others are the terminal branches of nerve fibres passing into the cortex from the white matter. These are called corticopetal fibres, and originate from nerve cells in the central ganglia, or from other parts of the cerebral cortex. The nerve fibres of the superficial lamina, and other strata in which the fibres are arranged tangentially, serve as association fibres, connecting different areas of the cortex with one another. They also connect fibres conveying sensory impulses reaching the cortex from the central ganglia or other parts with the cells which give rise to the efferent or outgoing impulses. Certain of these efferent, corticifugal fibres spring from the basal ends of the large pyramidal cells of Betz, present in the motor region of the cortex. They course inwards through the white matter to the internal capsule, where they converge to form the pyramidal tract. Other efferent fibres pass, by the corpus callosum, to the cortex of the opposite cerebral hemisphere.

In animals the degree of lamination and differentiation of the nerve-cells in the cortex appears to correspond with the stage of evolution attained by the particular species. The cortex is thicker and more highly evolved in man and the higher types of mammals than in lower forms. Moreover, in the development of the cortex, stratification begins about the sixth month of foetal life, when the convolutions first appear, and differentiation continues, not only during the later months of foetal life, but for a considerable period after birth. The more superficial strata containing the pyramidal cells are developed latest, and the human cortex is specially characterized by the great development of these cells.

**Weight of the Brain.**—The weight of the brain varies with age, stature, body-weight, sex and race. It is also influenced by

congestion of the blood-vessels, degenerative changes and atrophy. At birth the brain weighs approximately 380 grammes, and is 12.4% of the body weight. The entire brain, with the pia arachnoid of an adult British male, weighs approximately 1,409 g. or 49.6 oz., and of a female, 1,263 g. or 44.5 oz. The average stature and bodyweight of the female, however, is less than that of the male, and when these factors are allowed for the size and weight of the brain in the two sexes are approximately equal. The influence of age on brain weight is considerable. The growth of the brain is very rapid during the first three years, slightly less rapid up to the seventh year, when it is not far off its full weight. After this the increase is very gradual, its prime being usually attained, in males, by the 20th year, and in females somewhat earlier. From this period onward, in both sexes, there is a continuous diminution in the average brain weight of, approximately, 1 gm. per annum.

Tall people have heavier brains than short, but, relatively to their height, short people have larger heads and brains than tall. Many men of conspicuous ability have had brains of large size, e.g., Cuvier (1,830 grm.), but on the other hand the brain of Anatole France, who died, aged 81, weighed, without the membranes, only 1,017 grm.; by adding 60 grm. for the weight of the membranes, and 61 grm. to allow for shrinkage due to age, his brain may be estimated to have weighed, at the age of 20, no more than about 1,138 grammes. Nevertheless, averages calculated from groups, e.g., scholarship and prizemen, average, and below average ability, show statistically that there is a small, though measurable correlation between large size of head and a high intelligence. The relation becomes still more apparent when the heads of the intellectual classes are compared with those of the lower classes, and more particularly the inmates of workhouse infirmaries and congenital idiots. The microcephalic type of the latter may have brains weighing only 300 grammes.

**Development of the Brain.**—The central nervous system originates as an axial thickening of the ectoderm covering the dorsal surface of the embryonic area. This is the neural or medullary plate and is continuous on each side with the ectoderm, which will become the epidermis. The edges of the neural plate soon become raised, so that the axial band is converted into a longitudinal groove. This is the medullary groove and already at its anterior end shows three enlargements which are separated by a couple of constrictions. These indicate the site of the primary divisions of the embryonic brain, namely:—the forebrain or prosencephalon;

midbrain or mesencephalon; and hindbrain or rhombencephalon. There is also an indication on each side of the forebrain of the optic vesicle.

The medullary groove later becomes converted into a closed tube, which is named the medullary or neural canal, by the folding inwards and union of its edges. The union commences in the region of the neck and extends headward and tailward. The lumen

involve the whole thickness of the neural tube.

The stage with three primary vesicles soon becomes modified by subdivision of the forebrain into an anterior telencephalon and a posterior thalamencephalon; the hindbrain also divides into the metencephalon and myelencephalon. The telencephalon gives rise to the optic vesicles, olfactory lobes and hemisphere vesicles. The thalamencephalon forms the region of the brain surrounding the posterior part of the third ventricle behind the foramina of Monro. It includes the optic thalami, geniculate bodies, the pineal organ and cerebral lobe of the pituitary body. The metencephalon comprises the pons Varolii, part of the fourth ventricle, and the cerebellum; the myelencephalon corresponds to the medulla oblongata.

In transverse section the developing medullary tube is seen to consist of left and right lateral plates, between which is the central canal of the spinal cord. The lateral plates are joined at their dorsal margins by a thin roof plate, and along their ventral margins by a similar thin floor plate. These close in the central canal behind and in front. A cross section of the canal at this stage of development is diamond-shaped, with the dorsoventral diameter much longer than the transverse diameter. The wide angles on each side of the diamond correspond to a longitudinal groove on the inner surface of each lateral plate. This is the sulcus limitans and runs the whole length of the spinal cord. It is continued forward on the floor of the fourth ventricle, where it forms the fovea inferior and fovea superior (fig. 2), and finally on to the sides of the aqueduct of Sylvius in the midbrain. The groove is of great regional importance, as it marks off the ventral or basal part of the brain and spinal cord, which gives origin to motor nerve fibres, from the dorsal or alar part which receives the sensory fibres.

**Further Differentiation.**—A transverse section of the developing neural tube also shows three important zones. An inner or germinal zone; middle or mantle zone and an outer or marginal zone. The germinal zone is characterized by actively dividing nuclei. The middle zone forms the central grey matter of the cord and contains a large number of oval nuclei embedded in the supporting tissue. The marginal zone consists at first only of a fine network of supporting or neuroglial fibres. Later, it is traversed by white medullated fibres forming the columns of white matter.

These zones are present in the early stages throughout the whole extent of the neural tube, but the primary relations are considerably modified in the brain by the migration of nerve cells and nerve fibres from one zone into the other. Thus the inner zone forms the ependyma or lining membrane of the central canal of the spinal cord and ventricles of the brain. In certain situations in the brain, however, it is invaginated into the cavities of the ventricles, and modified so as to form the choroidal epithelium. Moreover, that part of the grey matter which forms the cortex of the cerebral hemispheres is situated on the surface of the brain and superficial to the white matter. This modification is brought about by the migration of nuclei from the mantle zone into the superficial strata of the marginal or outer zone. White fibres may also invade the territory of the grey matter, as in the formation of the internal capsule and pyramidal tracts. Portions of grey matter may thus be displaced from their original position, so that the primary position of the parts becomes obscured.

In the later stages of development the primary flexures of the brain become, to a large extent, straightened out, and the whole form of the brain becomes modified by the enlargement of the cerebral hemispheres.

**Hindbrain and Roofplate.**—In the hindbrain a remarkable change occurs in the position of the lateral walls of the neural tube, whereby their dorsal margins formed by the alar laminae become widely separated. Each lateral plate is rotated outward through an angle of  $90^\circ$  by a hinge movement, as in opening a book. The surfaces originally directed towards the median plane, thus become directed dorsally, and now form the floor of the lozenge-shaped fourth ventricle. The sulcus limitans still separates the basal (motor) and alar (sensory) region, but these, instead of being ventral and dorsal, are now internal and external (fig. 2.).

The roof plate also becomes greatly modified, becoming thinned out and stretched so as to form a delicate epithelial lamina, which

FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY"

FIG. 10.—HORIZONTAL SECTION OF RIGHT CEREBRAL HEMISPHERE  
Diagram shows the relations of the internal capsule to the thalamus and to the caudate and lenticular nuclei

of this tube is dilated at one end to form the ventricles of the brain, while in the rest of its extent it remains narrow and forms the central canal of the spinal cord. As the margins of the medullary groove unite to form the medullary canal, a continuous lamina of epithelium grows outwards on each side of the spinal cord and posterior part of the brain. This is the neural crest. It afterwards becomes segmented, and gives origin to the sensory ganglia on the posterior roots of the spinal nerves, the sensory fibres of the spinal nerves, and the ganglia and nerve fibres of the sympathetic system. It also takes part in the formation of some of the ganglia and nerve fibres of the cranial nerves.

It is of interest to note in this connection that the hypoglossal nerve which, in the adult, is a purely motor nerve for the supply of the muscles of the tongue, in the embryo has a posterior or sensory root with a rudimentary ganglion upon it (Froriep). This afterwards disappears, but its temporary presence in the embryo indicates that the nerve was primarily composed of both motor and sensory fibres and that it is homologous with the spinal nerves.

**Early Stages.**—In the early stages of development the brain presents certain flexures which involve the longitudinal axis of the neural tube. The first of these is the cephalic flexure, which is a forward bend round the anterior end of the notochord. It is followed by the cervical flexure at the junction of the brain with the spinal cord, which is also in a forward direction. Between is the pontine flexure, which is in the reverse direction and does not

is blended with the overlying pia mater. A part of this membrane becomes infolded just behind the cerebellum to form the choroid plexus of the fourth ventricle. The anterior part of the roof plate with the adjoining portion of the alar lamina becomes thickened to form the cerebellum, which is thus connected with the sensory tracts, and more especially with incoming impulses from the vestibular portion of the eighth cranial nerve. The

FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY"

FIG. 11.—DIAGRAM OF CEREBRAL CORTEX, SHOWING THE ARRANGEMENT AND CONNECTIONS OF THE NERVE CELLS ON THE LEFT, AND OF THE FIBRES ON THE RIGHT SIDE

median and lateral openings in the roof of the fourth ventricle are formed, secondarily, by a breaking down of the epithelial membrane. The cerebrospinal fluid is thus able to pass from the ventricles into the spaces of the subarachnoid tissue outside.

**Midbrain and Thalamencephalon.**—The midbrain in a 10 mm. human embryo is characterized by the relatively large size of its central canal and its prominent position on the surface of the brain. At a later stage, owing to the growth through it of tracts of nerve fibres, from the cerebral hemispheres, cerebellum and pons Varoli, the walls of the canal become greatly increased in thickness, and the lumen becomes relatively small (fig. 6). Moreover, in the later months of foetal life, the midbrain becomes completely covered over and concealed by the backward growth of the corpus callosum and cerebral hemispheres.

The thalamencephalon appears to undergo less change from the primary form of the neural tube than either the midbrain or hindbrain. It differs, however, in the absence of the basal or motor

region, the motor functions of this part having been transferred to the motor area of the telencephalon. In the early stages of development the roof and lateral surfaces of the thalamencephalon are exposed on the superficial aspect of the brain. About the third month, however, the cerebral hemispheres, with the developing corpus callosum and fornix grow backward over the thalamencephalon, mesencephalon and cerebellum, carrying with them a covering of pia mater. This fuses with the pia mater covering the thalamencephalon so as to form a triangular fold, the velum interpositum, or tela chorioidea, from which the choroid plexuses of the third and lateral ventricles are formed.

The hemisphere vesicles are at first quite small and open by a relatively large aperture, the foramen of Monro, into the third ventricle. The latter is limited in front by a thin membrane, the lamina terminalis, so named because it at first forms the anterior end of the brain. Later the hemispheres grow forward on each side of it and it is left at the bottom of the great longitudinal fissure. As the hemispheres enlarge forwards, upwards and backwards nerve fibres are developed between them, which cross in the lamina terminalis. These form the anterior commissure, the hippocampal commissure of the fornix, and the corpus callosum. The mode of development of these and of the fornix and septum pellucidum is indicated in figs. 4 and 8.

**Development of the Pituitary Gland** (fig. 4) (*See DUCTLESS GLANDS*).—This body is composed of two parts: an oral or anterior lobe, which is glandular in structure, and a cerebral or posterior lobe composed of neuroglia. The organ is present in all vertebrate animals, and is developed very early. Thus in the human embryo of four weeks the oral portion appears as a flattened, flask-shaped diverticulum, the pouch of Rathke, which arises from the ectoderm of the primitive mouth cavity or stomodaeum. This comes in contact with the neural ectoderm forming the floor of the third ventricle, behind the optic decussation and in front of the anterior end of the notochord. Later the neural ectoderm gives rise to a hollow diverticulum, the posterior lobe, which is connected to the brain by a funnel shaped stalk, the infundibulum (figs. 4 and 9). The infundibulum then becomes surrounded on the front and sides by the vesicular part of the pouch of Rathke. That part of the pouch which comes in contact with the cerebral lobe is called the paraneural part or pars intermedia.

The parts on each side which become applied to the infundibular part of the floor of the third ventricle are the lateral or tubular lobes. The vesicular part of the pouch soon becomes cut off from the roof of the mouth cavity by the degeneration of its stalk. About the seventh or eighth week the vesicle becomes further modified by the outgrowth from it of numerous branching processes which invade the surrounding tissue. The processes are at first hollow and lined by epithelial cells. Later the mesodermal tissue between the processes becomes vascularized, and the lumina of the processes and the main central cavity gradually become obliterated. The cavity of the posterior lobe also disappears, with the exception of a small recess in the floor of the fourth ventricle, which corresponds to the attachment of the infundibulum. In the adult the interior of the cerebral lobe is occupied by a loose network of supporting neuroglia, and contains no nervous tissue, except fibres of the sympathetic system which accompany the vessels.

The meshes of the network contain a clear fluid. In the paraneural part or pars intermedia, the epithelium is frequently arranged in the form of closed vesicles containing colloid material and this substance has sometimes been observed in the posterior lobe and in the region of the third ventricle, close to the infundibulum, more especially in those animals in which the lumen of the cerebral lobe persists and remains in continuity with the cavity of the ventricle. The origin of the pituitary gland presents one of the most interesting problems of comparative embryology, references to the literature on which will be found in any of the standard works on zoology and embryology mentioned in the bibliography.

**Pineal Organ or Epiphysis.**—The pineal body of the human brain is a small conical structure (fig. 4) which springs from the posterior part of the roof of the third ventricle and projects back-

FROM LANKESTER, "TREATISE ON ZOOLOGY" BY PERMISSION OF A. & C. BLACK

FIG. 12

wards over the superior quadrigeminal bodies. It consists of rounded epithelial cells which are arranged in an alveolar manner. Between the alveoli or follicles is a supporting tissue enclosing thin-walled blood vessels, and frequently containing also deposits of calcareous salts. These form small spherical bodies which show, on section, a concentric laminated structure. They are known as "brain sand" and in old subjects are commonly found also in the choroid plexuses, pia arachnoid and other parts of the brain.

The pineal body of man is a vestigial organ which represents a more highly evolved apparatus in lower types of living vertebrates, and probably a still more highly evolved apparatus in certain extinct reptiles such as the Ichthyosaurus. In one living reptile, the Tuatera, the pineal apparatus consists of two distinct (Sphenodon) organs—a glandular organ, the epiphysis, which is the structure present in the human brain, and a sensory organ, the "pineal eye"; this is situated in the parietal foramen, a central aperture in the vault of the skull, immediately beneath the scales covering the surface of the head.

In some of the lower vertebrate animals the pineal organ is bilateral, and it is believed that the ancestors of vertebrate animals possessed a pair of parietal eyes which may have been serially homologous with the paired vertebrate eyes. Transitional stages in the evolution of the pineal body from a bilateral to a mesial organ have been described by Cameron in the Amphibia.

**Comparative Anatomy.**—In the lowest types of vertebrate animals, the brain is tubular in form and resembles an early developmental stage of the brain in higher vertebrates. In the small lancelet or *Amphioxus* (*q.v.*) the brain consists of a median cerebral vesicle, the cavity of which is continuous with the central canal of the spinal cord. In the larval stage, an opening lined by ciliated epithelium, the neuropore, lies at the bottom of a funnel-shaped depression, the olfactory pit. Viewed from the outside, there appears to be no distinction between brain and spinal cord.

In front, at the pointed anterior end of the brain, is a median pigmented area. This is regarded as the rudiment of a median eye. A thickening of epithelium in the floor of the ventricle probably represents the infundibulum of the pituitary body. There are only two pairs of cranial nerves, both of which are sensory.

**Cyclostomes.**—In the cyclostomes, of which the lamprey (*Petromyzon*) may be taken as an example, the brain is much more highly developed. There is a distinction into forebrain, mid-brain and hindbrain. There are well developed eyes with optic nerves ending in optic lobes (fig. 12). In the larva the fibres of the optic nerves, instead of crossing to the optic tract and lobe of the opposite side, as in higher vertebrates, appear to pass back to the optic lobe of the same side. It is probable, however, that in the later stages of development a decussation of some of the deeper fibres occurs in the floor of the fourth ventricle. The forebrain presents on each side two hollow vesicles, namely, the olfactory lobe of large size, and a rudimentary cerebral hemisphere behind. The two cerebral hemispheres are joined across the median plane by the lamina terminalis, in which there is already evolved a small anterior commissure.

On the dorsal aspect of the thalamencephalon are two oval masses, the ganglia habenulae. The right of these is much larger than the left and from it a narrow stalk runs forward, to terminate in a minute pineal organ which contains vestiges of a pigmented retina and lens. A second pineal stalk which is even more vestigial than the right projects forward from the small left ganglion. There is also an indication of an additional outgrowth in front of the pineal organ, the paraphysis. The pituitary body is formed from a single median pouch, the pituitary sac, which opens primarily on the ventral aspect of the head, between the olfactory sac in front and the primitive mouth behind.

Later the pituitary sac sends out small follicular processes which fuse with the infundibulum and form, with the latter, the com-

pound pituitary gland. In the course of development the original openings of the pituitary and olfactory sacs are displaced from the ventral to the dorsal aspect of the head. In the hindbrain a rudimentary cerebellum is present, which appears as a transverse bar at the anterior boundary of the roof of the fourth ventricle. The choroid plexuses are well developed and consist of three invagina-

FIG. 14.—BRAIN OF ALLIGATOR. WHILE THERE IS A CONSIDERABLE ADVANCE IN THE DEVELOPMENT OF THE CEREBRAL HEMISPHERES, THE CEREBELLUM IS NOT SO HIGHLY DEVELOPED AS IN THE SHARKS

A. From above. B. From below. C. From the side

ther advanced (fig. 13). The development is chiefly in the olfactory part of the brain and the cerebellum. Although the eyes are fully developed, smell is probably the dominant sense, since the

olfactory bulbs and tracts are enormous and project as large hollow outgrowths from each side of the forebrain. There is also a remarkable development of the cerebellum, more especially in the Porbeagle shark (*Lamna*), in which the cerebellar cortex is highly convoluted. The cerebral hemispheres are much larger than in the lamprey, the corpora striata are developed, and a roof plate or pallium is present; but as yet there is no differentiation of cortical layers. There is only one pineal stalk. The fibres of the optic nerves cross one another without intersection of fibres.

The brain of the Teleostei, or fishes having a bony skeleton, is in some respects not so far advanced as that of the cartilaginous fishes. The cerebral hemispheres and olfactory lobes are small. The optic lobes are, however, enormously developed, and the optic nerves cross one another without intersection of fibres.

In the mud fishes, or Dipnoi, the brain is elongated and tubular in form, the olfactory lobes large, and the cerebellum small. The brain, as might be expected, resembles in some respects that of the Amphibia.

**Amphibia and Reptilia.**—In the Amphibia the brain is tubular and does not show any distinct advance on the type characteristic of fishes, and in some respects, e.g., the development of the cerebellum, is distinctly inferior to that of *Lamna*. The olfac-

FROM WIEDERSHEIM AND PARKER, "COMPARATIVE ANATOMY OF VERTEBRATES" (MACMILLAN)

FIG. 15.—THE BRAIN OF A PIGEON SEEN FROM BELOW, ABOVE AND FROM THE SIDE

The cerebral hemispheres, optic lobes, optic tracts and cerebellum are of large size. The olfactory lobes are less developed than in the fishes and reptiles

tory lobes are large and in the frog's brain are fused in the median plane. In the lamina terminalis is developed an anterior or ventral commissure, and above this a dorsal or hippocampal commissure. The formation of the latter corresponds to the appearance of a small mass of cells in the superficial stratum of the median wall of the pallium. This is regarded by Osborn as the first indication of the hippocampal cortex. The epiphysis which is present in the larva disappears in the adult animal. There is a well developed infundibulum and hypophysis. The optic tracts and lobes

are of large size. The cerebellum appears as a small transverse bar in the anterior part of the roof of the fourth ventricle, and closely resembles that of the human embryo at the fourth week.

In the Reptilia (fig. 14) the cerebral hemispheres are more highly differentiated. The mesial surface of each hemisphere shows an upper hippocampal zone, a lower olfactory tubercle, and an intermediate part, the paraterminal body or precommissural

lobes and backwards over the thalamencephalon, midbrain and cerebellum. Convolutions and fissures appear. There are a dorsal and ventral commissure, fimbria and gyrus dentatus. The cerebellum is well developed, presenting numerous folia and a conspicuous flocculus. In the spiny ant eater (*Echidna*), which is nocturnal in its habits, the optic nerves are extremely small, but there is an enormous development of the olfactory bulbs and tubercles.

**Marsupialia and Insectivora.**—In the Marsupialia the type of brain varies much, apparently according to the habits of the different species. Thus in the Tasmanian devil (*Sarcophilus*), described by Elliot Smith as an "offal eating animal," there is an enormous development of the olfactory bulbs and region of the brain termed rhinencephalon; in kangaroos (*Macropodidae*), there is a great development of the neopallium and cerebellum.

The Insectivora are remarkable for the very large size of their olfactory organs. In the mole the optic nerves and tracts and the superior corpora quadrigemina are poorly developed. The influence on the brain of change of habit in two members of the same family, the jumping shrew and the tree shrew, is strikingly depicted in the illustrations (fig. 16). (G. Elliot Smith, *Essays on the Evolution of Man* [1927].) The accompanying drawings of the brains of higher mammals, *Tarsius spectrum* and the marmoset, show the increase in the visual, acoustic and tactile areas which has taken place in these animals, and especially in the latter, of the prefrontal and association areas.

**Higher Mammals.**—The surface of the brain in mammalian animals varies greatly with regard to the convolutionary pattern. In some the hemispheres are smooth, e.g., the manatee, the lesser ant eater and the marmoset; in others, highly convoluted, e.g., the whales and dolphins, and certain ungulates such as the elephant; others are intermediate in this respect. The degree of convolution is partly dependent on the size of the body. As a rule

FROM G. E. SMITH, "EVOLUTION OF MAN" BY PERMISSION OF OXFORD UNIVERSITY PRESS  
FIG. 16.—DIAGRAMS SHOWING THE EFFECTS OF HABIT ON THE BRAIN. Animals dependent on the sense of smell have a highly developed olfactory region. Those which are dependent on the sense of sight, have a highly developed and extensive visual area. In monkeys and in man there is a marked increase in the prefrontal area, which is concerned in the visual control of skilled movements.

area. On the upper part of the outer or lateral surface is a limited area, termed by Elliot Smith the neopallium. This is the forerunner of the large sensory and motor areas of the cortex which form the main part of the cerebral hemispheres in the higher mammalia. Below the neopallium is the piriform lobe, which is olfactory in function and corresponds to the uncus of the human brain. The corpora striata are large, and there is an indication of differentiation into caudate nucleus, globus pallidus and putamen. In the Lacertilia the pineal organ is more highly developed than in any living vertebrate animal. There is, however, no evidence of its use as an organ of sight.

**Birds.**—In birds (fig. 15), the cerebral hemispheres, optic lobes and cerebellum are large. The surface of the cerebral hemispheres is smooth, and their bulk depends largely on the great size of the corpora striata. The cerebellum consists of a large central lobe or vermis, crossed by a series of parallel fissures, and on each side a small but well-defined flocculus. The olfactory lobes are extremely small, and, judging from the early development and large size of the optic vesicles and the optic nerves and tracts, vision is the dominant sense.

**Monotremes.**—In the lowest Mammalia, represented by *Ornithorhynchus* and *Echidna*, the cerebral hemispheres are greatly developed. They extend forward over the olfactory

FIG. 17.—DIAGRAM OF THE TOPOGRAPHY OF THE MAIN GROUPS OF FOCI IN THE MOTOR FIELD OF A CHIMPANZEE

large animals have highly convoluted brains; small animals, smooth brains. There is also a definite relation between the number of white fibres in the centre of the hemispheres and the number of nerve cells in the grey cortex on the surface.

In some animals, e.g., the Cetacea, with a highly convoluted pattern, the grey cortex is very thin. In the higher types of animals it is usually thicker and much more highly differentiated. The brain of the chimpanzee (fig. 17) closely resembles the convolutionary pattern of the human brain. In most apes there is an extension forward of the peristriae (visual) area of the cortex on the

outer side of the occipital lobe. This encroaches on and overlaps the parietal lobe and occipito-parietal fissure. It thus produces a transverse or lunate sulcus. This is the simian fissure or "affenspalte," and is represented in the human subject by a small and variable fissure (*S. lunatus*) which usually lies some distance behind, and external to, the external parieto-occipital fissure and is not continuous with it. The human brain is distinguished anatomically from that of the higher apes by its large size and great development of the prefrontal region. It is also characterized by a much greater complexity in the microscopical structure of the cerebral cortex. Mentally man is distinguished from the apes by the faculty of speech and by much greater power of reasoning, concentration and appreciation. See MAMMALIA; PRIMATES.

**BRAINERD, EZRA** (1844–1924), American botanist and educator, was born at St. Albans, Vt., Dec. 17, 1844. He graduated at Middlebury college in 1864 and at Andover theological seminary in 1867. Entering the faculty of Middlebury college, he was professor of rhetoric and English literature from 1868 to 1880 and professor of applied mathematics and physics from 1880 to 1886. From 1885 to 1908 he was president of the college. He made important contributions to the geology and botany of Vermont, and through extensive researches on the native species and their hybrids became the foremost botanical authority on North American violets. His experimental study of hybridity as exhibited in violets is one of the most valuable as yet made for any group of North American plants. Besides a large number of scientific papers, chiefly botanical, he published *The Violets of North America* (1921) and *Some Natural Violet Hybrids of North America* (1924). He also contributed sections on violets to standard North American floras. He died at Middlebury, Vt., on Dec. 8, 1924.

**BRAINERD**, a city of central Minnesota, U.S.A., on the E. bank of the Mississippi river, at an altitude of 1,200ft., 128m. N.N.W. of Minneapolis; the county seat of Crow Wing county. It is served by the Northern Pacific and the Minnesota and International railways. Population in 1930 was 10,221. Brainerd is the metropolis of the Cuyuna iron range, which runs through the city, and of the agricultural population which is displacing the lumber-jacks and hunters of 1900–10. The principal industries are the railway shops and tie-treating plant of the Northern Pacific, and a pulp and paper mill with a daily capacity of 50 tons of pulp and 45 tons of finished paper.

Within easy driving distance are 700 lakes and many summer resorts. The 47 iron mines, many of which are of the open-pit type, are clustered around the villages of Riverton, Ironton, Crosby, Deerwood, Manganeese, Trommald, and Cuyuna, from 12 to 20m. N.E. of Brainerd. From 1906, when iron was discovered here, through 1925, 16,322,974 gross tons were mined. Brainerd was settled in 1870; was named after David Brainerd; and was chartered as a city in 1883.

**BRAIN-FEVER BIRD** (*Hierococcyx varius*), an Indian cuckoo superficially resembling the Indian sparrow hawk. It takes its name from the suggested effect of its constantly reiterated cries. Like the European cuckoo (*q.v.*), it is parasitic, the usual hosts being babblers.

**BRAIN, SURGERY OF.** It is common knowledge that surgery as a whole was "released" by the discoveries of Pasteur and Lister, so that the remarkable technical achievements of the surgeon to-day are the result of no more than fifty years' collective experience. Attention was at first focussed chiefly on the surgery of the abdomen and limbs, and so great and so rapid were the advances made in these spheres that something approaching technical perfection has been reached. The surgery of the

brain made slower progress because the problems involved were of a much more intricate nature, cases were fewer, and accurate diagnosis, an absolute pre-requisite for good surgery, more difficult. The bony skull renders exposure difficult, access is often far from perfect, and a very small error in localization of the lesion suffices to mar the result. Add to this the fact that the tension inside the skull in tumour cases is greatly increased, so that the brain tends to bulge into the opening made and render exploration difficult, unless the pathological lesion happens to be superficial.

**The Closed Cranial Box.**—The brain is enclosed within a bone capsule and enveloped in membranes which protect it and carry blood vessels to it. A thin film of cerebro-spinal fluid covers it, but normally so accurately does the skull fit the brain that the convolutions impress the bone, and a plaster cast of the interior of a dried skull reproduces faintly the pattern of the brain which once inhabited it. This fact has been of great value to the comparative- and palaeo-anatomist. In spite of this close fitment, there is normally no pressure of bone on the brain. As the brain develops and expands the bone is its servant and never its master; we no longer believe that the bone may stop growing before the brain is fully developed. Thus in a case of maldevelopment of the skull with an immature brain within, we now believe the immaturity of the brain to be the primary factor. Incisions through the bone with the object of releasing a supposedly imprisoned brain have been done in the past but without profit, for the intervention was based on wrong premises.

It will be understood that there is very little room inside the skull to accommodate any extra bulk, such as a tumour, abscess, collection of blood or fluid and indeed any such addition will invariably produce recognizable effects.

**Trephining or Trepanning.**—The art of making openings in the skull was known to the ancients, as many recently recovered crania indisputably inform us. The methods employed have been the subject of much speculation and argument, and seem to have ranged from attrition with flint implements to drilling and cross-hatching. By trepanation, an obsolescent word, we mean the making of a hole by chisel or gouge; by trephining, the cutting out of a disk of bone by a special ring-saw. To-day the majority of surgeons use a drill and burrs, hand or electrically driven; great ingenuity is being shown in planning rapid and safe methods. It might be thought that any competent surgical engineer could easily invent some power-driven tool which would reduce the time and effort required to cut a flap of bone (which ought to be replaceable). The problem is far from simple, however, as the dura mater adheres to the inner surface of the bone sufficiently strongly to necessitate much safe-guarding, for it is essential that the brain and its coverings should remain uninjured. A number of clever appliances are in existence, but, as is often the case, the more ingenious the less generally useful are they.

The operation in most general use to-day is that known as the "osteoplastic flap," where a flap of scalp and bone of large diameter is turned down and when carefully replaced gives an excellent cosmetic result. The exposed dura mater is then incised and the convolutions laid bare. A tumour may at once be seen but if not the brain tissue is carefully probed to detect a difference in resistance. A cyst may thus be encountered and drained. It is surprising how little disturbance this gentle exploration causes if done at a well chosen spot. The whole procedure can be carried out under local anaesthesia. Brain tissue is absolutely insensitive and can be cut without the conscious patient being aware of it. The dura mater and vessels are supplied with sensory nerves and it is only owing to this that headache is possible.

The common subtemporal decompression is done by splitting the fibres of the temporal muscle, boring or cutting through the bone, and enlarging the bony opening with nibbling forceps. The dura mater must be opened as it is so strong that, undivided, it will prevent the brain from prolapsing, and little or no relief of pressure will result. The pituitary gland tumour is attacked through a frontal flap or alternately through the nose after removal of the cartilage and bone in the nasal septum.

**Head Injuries.**—Head injuries are increasing in number owing to the development of mechanical transport and the accidents to all classes of the community which are its inevitable consequence. The skull possesses a considerable degree of elasticity and may be deformed for an instant by a blow without solution of continuity (*i.e.*, fracture). In that instant very serious damage may be inflicted on the brain, the problem in physics being one of hydro-dynamics on a fluid and semi-fluid content in a rigid container. Very often the skull is broken, but the immediate outlook for the patient and the longer view of his future depends very little on fracture, *per se*, but much more on the extent of the brain injury. For various reasons the floor or "base" of the skull breaks more readily than the cupola, and fractures of the cranial base are the common injuries. On the whole it may be laid down that objects of small mass and high velocity tend to produce local injury of the skull (depressed fractures), whilst those of great mass and low velocity tend to deform the skull as a whole and cause bursting fractures (Trotter and Wagstaffe) usually in the base but extending up from the point of impact. Treatment is essentially on conservative lines, except in depressed fractures.

Concussion, a condition characterised by unconsciousness and associated with shock, is the common result of severe cranio-cerebral injury. It varies in degree from momentary "stunning" (as when a boxer is knocked-out in the ring) to profound unconsciousness lasting hours or days. Delay in recovery is due to oedema of the brain, to the occurrence of minute haemorrhages dotted throughout, or rarely to a large local effusion of blood causing cerebral compression. The oedema is best treated by hypertonic salines (*see below*), the effusion by operation which, be it noted, is only occasionally indicated.

**Gun-Shot Wounds and Stab Wounds.**—The only pathway by which a stab can easily reach the brain is through the roof of the orbit, and many cases are on record of accidental injury by this route, for example, penetration by the ferrule of an umbrella, fall on a spike and so on. The danger of infection is great if the patient immediately survives as he often does.

In gun-shot wounds the great factor is the velocity and size of the missile. At short range the cranial capsule will positively burst in pieces, just as water will be ejected from a tub by the passage of a high velocity bullet. If the dura mater is torn (as it will be save with glancing wounds or a spent projectile) infection ensues unless an immediate operation is undertaken to excise the wound in scalp and bone and suck out spicules and diffuent brain matter. The projectile should be removed if it has not traversed too far but it must be most accurately localised by X-Rays first. The defects in the bone, results of gun-shot wounds and rarely of fractures, may call for closure by bone-grafts or celluloid plates (Sargent), but the wounds must be long healed and sterile first.

**Cerebral Compression.**—It has been remarked that any effusion or growth inside the skull must soon compress the brain. The grey and white matter which constitutes the brain, though soft in texture, is incompressible as water (Monro-Kellie doctrine), so that only the fluids circulating within it, blood and cerebro-spinal fluid, can be squeezed out. Severe headache is the earliest symptom, and continued violent headache in a previously healthy person is always suspicious. Vomiting is a common accompaniment, owing to anaemia of the vital centres in the medulla oblongata. Congestion of the optic nerves is usually present and will lead to blindness if the condition is not relieved by removal of the cause or alternatively by the provision of an opening in the skull to reduce the pressure (decompression).

**Relief of Pressure.**—The commonest cause of raised intracranial pressure is tumour of the brain, by no means a rare affection. These growths produce local destructive effects from which the situation of the tumour may be deduced (disturbance of motion and sensation of various kinds). But their outstanding feature is the headache and general misery which they induce by developing in a confined space where there is no margin for any foreign or extra bulk. The local effects of brain tumours are dealt with elsewhere (*see NEUROPATHOLOGY*) as is their nature (*see*

**TUMOURS**). For our immediate purpose the important fact is that the majority are gliomas, arising from the supporting stroma of the cerebral tissue and possessing no capsule. This means that they cannot be enucleated without leaving tumour cells behind. Nor can a block-resection of sound tissue with the tumour enclosed be performed without inflicting severe and permanent disability on the sufferer, though this has been advocated (Dandy). Fortunately many gliomas grow very slowly so that if the main mass is removed relief for some time at least follows. Further, they show a tendency to degenerate into relatively benign cysts which may be tapped, and lastly, some types are sensitive to irradiation by X-rays or radium. The endothelioma, on the other hand, is benign and once removed does not recur, but unfortunately many lie in inaccessible positions and are extremely difficult problems technically. Pituitary tumours are also benign, but can rarely, if ever, be totally extirpated, whilst tumours arising from the auditory nerve are in similar case; fragmentary removals give most satisfactory results, and the patient often lives for years after the operation.

All intracranial tumours for one reason or another tend to interfere with vision, and indeed if left untreated, blindness is the almost uniform end. Operation to relieve pressure and save sight must be undertaken early. Generally the intervention will take the form of a decompression, a sufficiently wide opening being made in the skull and dura mater to allow the brain to bulge—a safety-valve as it were. Since the bulging brain needs protection the opening is best made beneath the temporal muscle (Cushing), and since haemorrhages may occur in the released area with consequent impairment of function the opening should be over a relatively "silent" area, such as the right temporal lobe. Up to recent years little more than this decompression was attempted but there is a growing tendency now to attack in addition the tumour itself. Even if it should be irremovable the resection of bone over it will allow more competent attack by post-operative radiation. It may be said that the results of surgery so far as concerns permanent cure leave much room for improvement, but the treatment of brain tumours is still relatively in its infancy. So far as concerns immediate relief from agonising headache, from failing vision and the like, the results are usually good.

**Hypertonic Solutions.**—In very bad cases the patient may be comatose and operation is not always then desirable, the brain tissue will veritably burst when the skull is opened so high is the tension. Such patients may be recalled to consciousness and better fitted for operation by the intravenous administration of hypertonic solutions. We owe this advance to Weed and McKibben who advocated the use of 15% salt solution intravenously. Fifty to one hundred c.cs. "pulls over" the excess fluid from the cerebro-spinal network and sometimes lowers tension remarkably. Glucose in 50% strength acts more slowly but for a longer time. This type of physiological medication is proving helpful in the surgery of tumours, for the fact that they cause such huge rises in brain pressure has militated against successful attack upon them. Were pressure normal, exploration and extirpation would be very much easier; hypertonic therapy marks a step in the desired direction.

**Ventriculography.**—A complete neurological examination calls for considerable co-operation on the part of the patient, and in those cases where a patient is too drowsy and ill to pay much heed to questions or respond to requests it is sometimes difficult to say just where a brain tumour may be. In such cases use may be made of ventriculography or cerebral pneumography. A small hole having been made, the lateral ventricle is punctured and cerebro-spinal fluid drawn off, a quantity of air equal to the amount of fluid extracted is injected and an X-ray will now show the ventricles clearly outlined. Deductions as to the position of the tumour may be drawn from the shape of the ventricle. The method is not without danger and the interpretation of the X-rays is often puzzling.

**Brain Abscess.**—Abscess of the brain usually forms by direct extension from a focus of disease in the skull, usually in an accessory air-sinus such as the mastoid antrum or frontal sinus. The mortality is high because the infection tends to spread into the

surrounding brain tissue as a septic encephalitis. The chief sites are the cerebellum and temporo-sphenoidal lobes. Sometimes abscesses arise in the brain by lodgement of septic particles from the lungs when purulent bronchitis (bronchiectasis) is present. Drainage of the abscess is the only logical and successful treatment, the result depending often on the nature of the infection rather than on perfection of technical skill.

**Epilepsy.**—Jacksonian epilepsy, localized muscle group convulsions due to a circumscribed lesion of the motor cortex, has received much attention from surgeons. In those cases where there is indeed a focus of irritation, operation usually does good, but many apparent Jacksonian attacks are manifestations of ordinary epilepsy which has so far no discovered pathological basis.

**Facial Neuralgia.**—There is no medical cure for trigeminal neuralgia; the only hope lies in some form of operation designed to block the passage of impulses along the nerve. This may be attained by alcohol injections, but after about a year this needs repeating for the nerve fibres regenerate. The only permanent cure is division of the sensory root of the great ganglion of the nerve (Gasserian ganglion), a much less severe operation than the removal of the ganglion which was the custom a few years ago. It is often possible to save the fibres supplying the eye. It is usual to give alcohol injections first to accustom the patient to the idea of numbness, for in neuralgia cases the more complete and lasting the anaesthesia obtained the more complete the cure. The deadening of the skin has no ill effects, but when the eye is totally anaesthetic it is very apt to become inflamed (neuro-paralytic keratitis) and requires careful attention. Protective glasses must be worn out-of-doors. Sufferers from severe neuralgia are usually well prepared for any sacrifice to be rid of the pain. No deformity follows the operations. (G. J.)

**BRAINTREE**, urban district, Essex, England; 45m. N.E. of London by a branch line from Witham of the L.N.E. railway. Pop. of urban district (1931) 8,912. The parish church of St. Michael is fine Early English with later additions. The bishops of London had formerly a palace here, but nothing remains. Silk and crepe manufactures have superseded that of woollen cloth introduced by Flemish refugees from the persecution of the duke of Alva, but iron workers, especially fitters, are now more numerous.

**BRAINTREE**, a town of Norfolk county, Massachusetts, U.S.A., 34.5sq.m. in area, about ten m. south of Boston. Its villages (Braintree, South Braintree, East Braintree and Braintree Highlands) are served by the New York, New Haven and Hartford railroad. The population was 10,580 in 1920, of whom 2,276 were foreign-born whites; 15,712 in 1930 Federal census. The assessed valuation of property in 1927 was \$18,000,000; and the manufactured products in 1925 (chiefly shoes, nails, leather, rubber and woollen goods) were valued at \$15,144,475. Braintree was incorporated in 1640, from land belonging to Boston, and was named after the town in England. In 1708 it was divided into the North Precinct (now Quincy) and the South Precinct. Quincy was separated from Braintree in 1792 and Randolph in 1793. Bog-iron was found here at an early date, and ironworks were established in 1644.

**BRAKE**, town of Germany, in Oldenburg, on the left bank of the Weser, about halfway between Bremen and the mouth of the river. Pop. 6,500. It was for centuries the port of Bremen, but has been largely superseded by Bremerhaven. Shipbuilding and fishing are carried on.

**BRAKE.** A means of controlling the speed of a movement, or of totally arresting it. Nearly all brakes act frictionally, though the opposition of a piston in a cylinder can be applied for retarding purposes, converting the cylinder into an air-compressor for the while. Dynamic braking is another non-frictional method,

an electric motor being caused to run as a generator, so checking the speed of a vehicle or a machine, or causing a total stop. Most friction brakes act on revolving elements, as wheels or drums, but slipper brakes pressing on flat surfaces are applied as for tramcars, mechanically or magnetically operated, and a pincer or forcep type grips each flank of a rack in some of the mountain railways. A rope also serves for the application of a brake device in a few cases.

**Band-brakes.**—A highly effective braking action can be obtained by the coiling of a rope around a drum, as may be seen at any docks, a man holding the free end of the rope, and allowing it to slip gradually. The more convenient application of this idea (a flexible steel band) is employed on winches, hoists, haulage and winding engines, cranes and motor vehicles; in order to increase the frictional effort and reduce heating, some kind of lining has to be fitted, as wood, leather, asbestos or one of the special compositions. The band fits externally in all ordinary examples, but when access of dirt, moisture and grit must be prevented, which is the requirement in motor-cars, an internal expanding type has the preference, the band being made in two or three parts, with a pivotal freedom. By the multiplication of power with a lever, plus the frictional effect of the band embracing a large diameter, a man by exercising moderate force at a handle or treadle can hold a load of several tons, and pay it out slowly or quickly by regulating his pressure. Fig. 1 may be noted to explain the essential features, the lever having its eye pivoted on a short shaft around which one end of the band is looped, while the other end is pinned a little way along the lever, being consequently pulled taut as the pedal is depressed. A balance-weight at the tail end frees the band when the foot releases the lever.

**Electro-mechanical Brakes.**—Electric cranes possess a similar kind of band-brake, but with a system of levers arranged so that a weight applies the band, excepting while the crane is working. As current is switched on, a solenoid acts on an electro-magnet and pulls the lever; directly current is switched off, or fails from any cause, the weight asserts itself again. By a hand release mechanism lowering may be done, and automatic over-winding gear is usually fitted, which has the effect of applying the brake should the load be lifted too near the jib or girders. Not only the lifting motion, but slewing, derricking and travelling motions generally have electro-mechanical brakes, an important factor in high-speed operation.

**Motor-car Brakes.**—A special class of brake-drum arrangement is built into many cars, with duplex shoes; for instance,

FIG. 1.—THE SIMPLE BAND OR STRAP BRAKE. FOR CRANES, HOISTS, HAULAGE ENGINES AND OTHER MECHANISMS

The driver, by pressing on the pedal, is able to control speed or effect a dead stop. The lining is of wood, leather, or asbestos fabric, greatly enhancing the grip

the pedal actuates shoes in drums on the four wheels, while the hand-lever operates separate shoes in the rear wheel drums. The diagram (fig. 2), gives a face view of a drum, with the spring-closed shoes, and the cam which spreads them apart. Rigid rods usually transmit the power from the hand-lever or pedal, but there is a class with steel ropes, termed a cable brake, forming the connection to the front and rear drums. Servo-mechanism operated from the gear-box works through clutchplates; first the rear brakes go on as the driver depresses the pedal, and then the clutch faces engage, and through levers augment the driver's

effort, and also put on the front-wheel brakes. Or a connection is made to the engine so as to obtain suction on a piston in a servo-motor, the valve for this coming into use as the driver gradually applies the brake. Fig. 3 shows the system of levers in the Dewandre mechanism. As the pedal is pushed over it draws lever A forward until the clearance between its boss and the pin B is taken up, the brakes going on by the pull of rod C, the top end

FIG. 2.—THE EXPANDING BAND BRAKE USED IN AUTOMOBILES  
This brake can be enclosed and protected from dirt and moisture. The partial twist of the cam forces the ends of the shoes apart and thus causes the friction-lining to grip against the interior of the drum

of which is really fulcrumed at the same spot B, though shown separated for clearness. Lever D now functions and places the suction manifold in communication with the brake cylinder, and the air is instantly sucked therefrom, setting the chain taut, and pulling over the bottom end of lever A.

In the Westinghouse vacuum-servo system a brake cylinder has one end open to atmosphere, the other end communicating with

FIG. 3.—DIAGRAM SHOWING PRINCIPLE OF THE VACUUM-SERVO BRAKE  
This form of power assistance is derived from the engine induction pipe, the partial vacuum drawing a piston backwards in the vacuum-servo cylinder. The piston is connected by a chain to a lever in the brake mechanism. The act of beginning to apply the brake by hand, causes the piston to suck backwards and complete the braking by power (By permission of "The Motor")

the engine induction-pipe through a control valve which regulates the resultant pressure on the piston. The brake levers are so devised that application of the brake pedal first brings the brake shoes into contact with the drums; then further foot pressure affects the control valve and opens the communication between induction-pipe and brake cylinder, thus causing the pressure of the atmosphere to move the piston and tighten the brakes still more. The braking force is directly dependent on the foot pressure.

The Westinghouse power-brake acts by air from a small compressor or by gas from the explosion chamber of a petrol engine. The control may be exercised either by foot-valve or hand-valve, and the brake-cylinder for each wheel is in the form of a pair of covers, one with foot to bolt to the chassis. The cylinder diameters range from 7in. to 12in. according to weight of vehicle. Instead of a sliding piston, there is a flexible diaphragm (see fig. 4) that moves as the pressure comes through the pipe joined up at the back cover, and pushes the rod outwards. The latter

FIG. 4.—CYLINDER AND DIAPHRAGM OF WESTINGHOUSE POWER BRAKE FOR MOTOR VEHICLES

Brake power is supplied by compressed air, or by gas taken from the explosion chamber of the engine cylinders and stored in a reservoir. On applying a hand or foot lever, the pressure is admitted behind the diaphragm, and so pushes out the piston-rod to operate the brake rigging

connects to a reversing crank, and so to the brake-rod. There is a slotted link fitment to the existing hand-brake to make this independent of the power-brake. Hydraulic power has the advantages of simple flexible pipe connections to the wheels, and a perfectly compensated action, since the pressure is equal in all directions. The Lockheed system, which is fitted to numerous makes of cars, has a small pump or master cylinder attached to the flywheel housing, forcing oil along pipes and through reinforced rubber connections to a cylinder in each brake assembly. Two small pistons in each cylinder expand the brake shoes, as evident from fig. 5 (from a Brocklebank car). The shoes are pivoted at the opposite side of the circle, in the usual manner. The pistons are 1½in. in diameter, and the normal pressure is about

BY COURTESY OF MESSRS. BROCKLEBANK AND RICHARDS, LTD.

FIG. 5.—DIAGRAM SHOWING ACTION OF LOCKHEED HYDRAULIC BRAKE  
Oil under pressure is supplied to the brake mechanism in each wheel drum and, entering between the two pistons, forces them apart, so expanding the pivoted brake shoes

roolb. per sq. in., rising to 350lb. in emergency. The fluid used is a mixture of equal parts of castor-oil and ether, and certain stabilising ingredients added.

**Railway Brakes.**—These comprise hand-lever brakes for small locomotives and trucks and wagons, screw and lever for vans and tenders, etc., steam for locomotives and sometimes tenders, Westinghouse air-brakes for whole trains, and vacuum brakes. The mixed system is also employed, an air-brake being used for the engine wheels, and vacuum for the train; or a steam-brake acts for the engine and vacuum for the train. A special valve

FIG. 6.—ENGINE FITTINGS FOR WESTINGHOUSE COMPRESSED AIR AUTOMATIC BRAKE

The essentials of this system are an air compressor and reservoir on the engine, and an auxiliary reservoir for each coach in the train. The brake is applied by reducing the pressure in the brake-pipe, which results in a movement of pistons in the triple-valves, allowing some of the compressed air in the auxiliary reservoirs to reach the pistons of the brake cylinders, so pressing blocks on the wheels. A breakaway of the train also causes the valves to act and apply the brakes.

enables air and vacuum brakes to act simultaneously. Hand action commonly occurs on wagons and vans, levers coupling up the hand-lever to the brake shoes, and on small locomotives; while the screw and lever affords more power, and is self-locking, and serves for small locomotives, the tenders and some vans. Steam is applied largely in the case of driving wheels, one cylinder actuating the rods for several shoes; a separate arrangement with flexible connection is frequently fitted to bogies; or, as alternative to the steam, the vacuum brake, or Westinghouse, takes charge of the engine wheels.

The Westinghouse automatic brake operates by compressed air furnished by a compressor on the engine, and stored in its main reservoir. The essential parts include those indicated in the diagram (fig. 6), commencing at the steam stop-valve, supplying steam through the air-compressor governor. The last-named shuts off steam when the required air pressure is reached. The compressor passes air into the main reservoir, which is directly connected by an isolating cock to the driver's brake-valve. This allows the air to pass through the adjacent feed-valve, adjusted to automatically maintain the desired pressure in the brake-pipe. Thence the air flows through feed grooves in the triple valve and into the auxiliary reservoir. Finally hose couplings connect up the brake-pipe throughout the train, with cocks to control the communication between the vehicles. The brake is applied by reducing the pressure in the brake-pipe, causing the pistons of the triple valve to move, and allow some of the air in the auxiliary reservoirs to gain access to the brake cylinders. Release occurs on restoring the air pressure in the brake-pipe, with the consequence that the triple valves close communication between auxiliary reservoirs and brake cylinders. For electric railways the brake is much the same as for steam, the only difference lying in the method of producing compressed air. The vacuum automatic brake is dependent on atmospheric pressure for its action, the brakes being normally kept off by the state of vacuum existing in the train-pipe and cylinders. An ejector on the engine produces the vacuum and maintains it constantly. As there is vacuum both above and below the pistons in the brake-cylinders, the pistons fall by gravity and the shoes remain off. But when atmospheric air is admitted to the train-pipe, by the driver or guard, or through a break-away, it closes a ball-valve in the piston so as to seal the upper side of the cylinder, and exerts pressure on the lower side of the piston, forcing it upwards and actuating the brake rods. The two conditions appear in fig. 7, the first view showing the

state with brakes off, the second with the air represented by dots. The object of the "rolling ring" of rubber is to make a perfect joint or packing without friction, and the release-valve serves to enable the brake to be released by hand.

**Tramcar Brakes.**—The hand-brake which applies shoes to the wheels of a tramcar suffers from limitations in regard to power, hence other systems must be utilized in conjunction with it. The regenerative method (causing the motors to act as generators) imposes a powerful braking effect. Or this may be combined with the operation of slippers magnetically clinging to the rails (an alternative to mechanically-applied slippers), thus affording axle braking combined with the powerful slipper drag. And sometimes the mechanism includes wheel shoe attachments, the drag of the magnets causing an application of the wheel brake blocks. The magnet coil is usually a large wire coil having a small number of turns, while for certain conditions a supplementary shunt or fine wire coil is added, energized by current from the line. With shunt winding the car can be brought completely to rest without having to apply the hand-brake.

**Other Types of Brake.**—The hand-brakes are utilised on hauling and winding engines, with pedal control, but the alternative is the "post" brake, fitted especially on large engines. This consists of two strong steel girders standing upright on each side of the brake-drum, and having wood blocks that press on a portion of the periphery on each side; rods and levers perform the tightening action. There are two drums on large engines, and the equipment includes heavy weights and a steam-brake cylinder; the overwinding gear takes care of the cage, and the brakes are sufficiently powerful to hold the engines against full steam.

Magnetic brakes operate by a direct pull between friction discs or shoes embracing a cylindrical drum, controlled by an electro-magnet. The result is quick and positive, and finds use on certain classes of electrically-driven machinery. This type is distinct from the electro-mechanical brake previously described.

Weston brakes, also termed disc or clutch brakes, are worked either magnetically, or by end pressure obtained from a screw or hand or pedal gear. The brake contains a number of friction discs, all brought into contact simultaneously, and giving a high gripping power which increases directly as the number of discs employed. This kind is much used on cranes. A "load" brake is one fitted to the heavier cranes, the movement of the load causing a sufficient freedom between the discs when lowering is being performed, but if the driving motor is stopped the friction

FIG. 7.—DIAGRAM OF THE VACUUM BRAKE: VACUUM CYLINDER SHOWING BRAKE OFF, AND ON

The vacuum produced in the train-pipe and the brake cylinders, allows the pistons of the latter to fall and through lever connections pull the brake shoes off the wheels. To destroy the vacuum, atmospheric air is sent into the train-pipe, and pushes the pistons up, so applying the brakes. A similar result is brought about, if the train should part, by the breaking of the coupling pipes.

reasserts itself and lowering ceases, the driver thus having perfect control.

Running-in brakes afford a means of imposing a load on an engine for a period, in order to bed down the bearings and piston-rings, in imitation of the actual service of the engine, but at a reduced speed. (For brakes used as dynamometers, see DYNAMOMETER.) (F. H.)

**Brake Shoes for Wheel-Truing.**—In making brake shoes for use on mining locomotive wheels pieces of "feralun" or artificial corundum (*q.v.*) are set in the mould, creating a shoe that will prevent the formation of false flanges on the wheel by constantly and uniformly grinding the wheels to the proper profile. The abrasive pieces must be set carefully to secure the desired result. With shoes of this type, braking efficiency is unimpaired and no time is wasted in keeping the locomotive in the repair shop for the purpose of wheel-truing.

**BRAKELOND, JOCELYN DE** (*fl.* 1200), English monk, and author of a chronicle narrating the fortunes of the monastery of Bury St. Edmunds between 1173 and 1202. He is known only through his own work. He was a native of Bury St. Edmunds; he served his novitiate under Samson of Tottington, took the habit in 1173, and became abbot's chaplain under Samson. The picture which he gives of his master, although coloured by enthusiastic admiration, is singularly frank and intimate. The unique interest of his work lies in the minuteness with which it describes the policy of a monastic administrator who was in his own day considered as a model.

Jocelyn has also been credited with an extant but unprinted tract on the election of Abbot Hugo (Harleian ms. 1005, fo. 165), but from internal evidence this seems to be an error. He mentions a (non-extant) work which he wrote, before the *Cronica*, on the miracles of St. Robert, a boy whom the Jews of Bury St. Edmunds were alleged to have murdered (1181).

See the editions of the *Cronica Jocelini de Brakelonda* by T. Arnold (in *Memorial of St. Edmund's Abbey*, vol. i. Rolls series, 1890), and by J. G. Rokewood (Camden Society, 1840); also Carlyle's *Past and Present*, book ii. A translation and notes are given in T. E. Tomlin's *Monastic and Social Life in the Twelfth Century in the Chronicle of Jocelyn de Brakelond* (1844). There is also a translation of Jocelyn by Sir E. Clarke (1907).

**BRAKEMAN**, in the United States, the employee on passenger trains of the railroad who assists the conductor and is in charge of the brakes. The forward brakeman is expected to keep the signal appliances in good working order and the rear brakeman on many trains performs the duties of a flagman. The brakeman

is expected also to help the conductor by announcing stations, helping passengers on and off trains and looking after their general comfort. He receives instructions from the train-master and is subject to the orders of the conductor while on the train. He must pass a physical examination with special stress laid upon eyesight and colour vision and must become familiar with signals and the terminology of train orders. Besides passenger train brakemen, there are yard brakemen who couple and uncouple cars in making up trains in the yards, and brakemen on freight trains who assist the freight train conductors. In 1920, there were approximately 927 brakemen per million of population in the United States.

**BRAMAH, JOSEPH** (1748–1814), English engineer and inventor, the son of a farmer, was born at Stainborough, Yorkshire, on April 13, 1748. He worked as a cabinet-maker in London, where he subsequently started business on his own account. His first patent for some improvements in the mechanism of water-closets was taken out in 1778. In 1784 he patented the lock known by his name, and in 1795 he invented the hydraulic press. For an important part of this, the collar which secured water-tightness between the plunger and the cylinder in which it worked, he was indebted to Henry Maudslay, one of his workmen, who also helped him in designing machines for the manufacture of his locks. In 1806 he devised for the Bank of England a numerical printing machine, specially adapted for bank-notes. Other inventions of his included the beer-engine for drawing beer, machinery for making aerated waters, planing machines, and improvements in steam-engines and boilers and in paper-making machinery. In 1785 he suggested the possibility of screw propulsion for ships, and in 1802 the hydraulic transmission of power; and he constructed waterworks at Norwich in 1790 and 1793. He died in London on Dec. 9, 1814.

**BRAMAH PRESS**, the practical application of Pascal's law that fluids transmit pressure equally in all directions. Joseph Bramah, about 1796, was able to construct a successful press, using a small pump plunger and conducting the water to a ram of much larger area. Each portion of the surface of the ram equal in area to that of the plunger therefore receives a like pressure, the difference in the two total areas greatly increasing the ram pressure. A force of a few pounds acting on the pump lever can thus be converted into hundreds of pounds force at the ram. The hand-operated presses built on this principle are extremely numerous, for various pressing and forming processes as required in the book-binding, printing, paper, leather, tobacco, tea, drug,

jewellery, engineering, and electrical trades. When a larger installation is required, or the powers are high, power-driven pumps are employed, or the supply is taken from accumulators or service mains. Nevertheless, hand-actuated presses can be had up to 300 tons power. Power-actuated types comprise those for punching and shearing, riveting, flanging, forging, and bending, baling, bundling, railway wheel forcing, and some special forms utilized in celluloid, cotton, tube, and munitions manufacture.

HAND OPERATED BRAMAH PRESS, USED IN BOOK-BINDING, PRINTING, PAPER, LEATHER, TOBACCO AND SIMILAR TRADES

Water is drawn into the pump through the valve, then forced, under pressure, through the pipe to the cylinder. Here, with its increased area and consequent increased pressure, it actuates the press-ram

There are three methods now by which cost of working is lessened, by comparison with the ordinary pump or accumulator supply above mentioned. (1) Water saving; by filling the press cylinder with ordinary supply and only turning on the pressure water at the moment of action, thus saving all the pressure water possible. (2) Fitting three cylinders for a big press and using one, two, or three according to needs, giving, for instance, either 200, 400, or 600 tons pressure. (3) Eliminating pumps and accumulators by the installation of a steam-intensifier. This consists of a large steam cylinder the piston of which operates a small hydraulic plunger, so that, for example, 150 lb. steam pressure can be made to give a hydraulic pressure of  $2\frac{1}{2}$  tons per square inch.

**BRAMANTE** or **BRAMANTE LAZZARI** (c. 1444-1514), Italian architect and painter, whose real name was Donato d'Agnolo, was born at Monte-Asdrualdo in Urbino. He studied painting probably under Mantegna or Piero della Francesca and in Milan came under the influence of Vincenzo Foppa. He appears to have studied architecture under Luciano da Laurano who was made chief architect at Urbino in 1468. He visited several of the towns of Lombardy, executing works of various degrees of importance. He remained in Milan from 1476 to 1499 and seems to have left for Rome about 1500. About this time the Cardinal Caraffa commissioned him to rebuild the cloister of the Convent della Pace and introduced him to Pope Alexander VI. He began to be consulted on nearly all the great architectural operations in Rome, and executed for the pope the palace of the Cancelleria or chancery. Under Julius II. Bramante's first large work was to unite the straggling buildings of the palace and the Belvedere by means of two long galleries or corridors enclosing a court. Unfortunately the foundations were not well laid, and the whole is now so much altered that it is hardly possible to distinguish the original design.

Besides executing numerous smaller works at Rome and Bologna, among which is a round temple in the cloister of San Pietro-a-Montorio, Bramante was called upon by Pope Julius to begin the rebuilding of St. Peter's. Bramante's designs were completed, and before his death he had erected the four great piers and their arches and finished the cornice and the vaulting of this portion; he also vaulted in the principal chapel. He had, therefore, laid down the main lines of the building. After his death on March 11, 1514, his design was much altered, in particular by Michelangelo.

See Pungileoni, *Memoire intorno alla vita ed alle opere di Bramante* (1836); H. Semper, *Donato Bramante* (Leipzig, 1879).

**BRAMBLE**: see BLACKBERRY.

**BRAMBLING** (*Fringilla montefringilla*), a finch (q.v.) allied to the chaffinch (q.v.), but slightly larger and with a more forked tail. Breeding in high northern latitudes, the brambling has a wide range in the Old World and occurs in Great Britain as a winter visitor.

**BRAMPTON** or **BRANDON**, SIR EDWARD, Anglo-Jewish adventurer of the 15th century. Born in Portugal of Jewish parentage, he came to England in maturity and was baptized under the auspices of King Edward IV., whose name he adopted. From 1468 to 1472, with a brief interval, he was an inmate of the Domus Conversorum in London, with an allowance of 1½d. a day. Subsequently, he entered public life, receiving a series of military appointments, and being rewarded with grants of land and of mercantile privileges. In 1482 he was appointed captain, keeper, and governor of Guernsey, which office he retained until the fall of the Lancastrians. He became a zealous partisan of Richard III., by whom favours were showered upon him, and was knighted in 1484. After the accession of Henry VII., he retired, first to the Low Countries, and then to Lisbon. At Middelburgh, there entered into his service a Flemish youth named Perkin Warbeck, who later, when he made his bid for the throne of England, made full use of his master's recollections of the court of Edward IV. In 1488, Brampton is found, incredibly enough, again resident in the Domus Conversorum in London: but he afterwards went back to Lisbon, where he entertained the English embassy in the following year. Through their medium, apparently, Sir Edward Brampton received a full pardon from Henry VII. in 1489, and returned to England. A son of his was knighted by the king at Winchester in 1500.

See *Transactions of the Jewish Historical Society of England*, ix. 143-162. (C. R.)

**BRAMPTON, HENRY HAWKINS, BARON** (1817-1907), English judge, was born at Hitchin on Sept. 14, 1817. Called to the bar at the Middle Temple in 1843, he joined the old home circuit and took silk in 1859. He was counsel in many of the famous trials of the reign of Queen Victoria: for example, in the Simon Bernard case (the Orsini plot); *Roupeil v. Waite*; the Overend-Gurney prosecutions; the convent case *Saurin v. Star*, 1869; the two Tichborne trials (1871-74) (see TICHBORNE CLAIMANT), and the will case of *Sugden v. Lord St. Leonards*. Hawkins was raised to the bench in 1876, and assigned to the then exchequer division of the High Court, not as baron (an appellation which was being abolished by the Judicature Act), but with the title of Sir Henry Hawkins. He was a great advocate rather than a great lawyer. His searching voice, his manner, and the variety of his facial expression, gave him a persuasive influence with juries, and as a cross examiner he was not surpassed. His knowledge of the criminal law was intimate, the reputation he gained as a "hanging" judge making him a terror to evil-doers. One of his earliest murder trials—the Penge case, *The Reg. v. Stanton and Rhodes* (1878),—aroused great controversy; four persons, two of them women, were sentenced to death but respited, one (Alice Rhodes), receiving a full pardon. For his conduct in this case, and, indeed, for the general tenor of his judicial career, he has been severely criticized by one of the greatest advocates of the Bar, Sir Edward Clarke, who was counsel in that case (see *The Story of My Life*, by Sir Edward Clarke, 1918). In 1898 he retired from the bench, and was raised to the peerage under the title of Baron Brampton. He frequently took part in determining House of Lords appeals.

Brampton died in London on Oct. 6, 1907. His own *Reminiscences* (1904, 2 vols.), ed. by Richard Harris, K.C., do Lord Brampton less than justice.

**BRAMPTON**, a market town of Cumberland, England, gm. E.N.E. of Carlisle, on a branch of the London and North-eastern railway. Population of parish (1931) 7,932. It is situated in a narrow valley opening upon that of the Irthing. Two miles N.E. of Brampton is the castle of Naworth built in the reign of Edward III. Overlooking a deep wooded ravine, with streams to the east and west, the great quadrangular castle was naturally defended except on the south, where it was rendered secure by a double moat and drawbridge. By marriage in 1577 with Lady Elizabeth Dacre it passed into the hands of William Howard, afterwards lord warden of the Marches, the "Belted Will" of Sir Walter Scott and the border ballads, who acquired great fame by his victories over the Scottish moss-troopers. The castle is the property of the earl of Carlisle and has numerous fine pictures.

Not far distant is Lanercost Priory, where in 1169 an Augustinian monastery was established. In 1311 Robert Bruce and his army were quartered here, and the priory was pillaged in 1346 by David, king of Scotland. From this time its prosperity declined until its dissolution by Henry VIII. The Early English church has a restored nave, but retains much fine carving. The chancel is ruined, but the interesting crypt is preserved. Brampton has an agricultural trade, small breweries, and manufactures a little cotton and tweed, but the majority of the population find employment as coal-miners and metal-workers on the neighbouring coal-field.

**BRAMWELL, GEORGE WILLIAM WILSHERE**  
**BRAMWELL**, BARON (1808-1892), English judge, was born in London on June 12, 1808, being the eldest son of a banker. He was educated privately, and after two years in a bank, was admitted as a student at Lincoln's Inn in 1830, and at the Inner Temple in 1836. At first he practised as a special pleader, but was called to the bar at both Inns in 1838. In 1850 he was appointed a member of the Common Law Procedure Commission, which resulted in the Common Law Procedure Act of 1852. This act he drafted jointly with Mr. (afterwards Mr. Justice) Willes, and thus began the abolition of the system of special pleading. In 1851 Lord Cranworth made Bramwell a queen's counsel, and the Inner Temple elected him a bencher. In 1853 he served on the royal commission to enquire into the assimilation of the mercantile laws of Scotland and England and the law of partnership, which had as its result the Companies Act of 1862. It was he who, during the sitting of this commission, suggested the addition of the word "limited" to the title of companies that sought to limit their liability, in order to prevent the danger to persons trading with them in ignorance of that limitation. As a queen's counsel Bramwell enjoyed a large practice, and in 1856 he was raised to the bench as a baron of the exchequer. In 1867, with Mr. Justice Blackburn and Sir John Coleridge, he was made a member of the judicature commission. In 1871 he refused a seat on the judicial committee of the privy council. In 1876 he was raised to the court of appeal, where he sat till the autumn of 1881. His decisions were always clear; he had a straightforward manner and a gift of trenchant speech. Among his important judgements are *Ryder v. Wombwell* (L. R. 3 Ex. 95); *R. v. Bradshaw* (14 Cox C. C. 84); *Household Fire Insurance Company v. Grant* (4 Ex. Div. 216); *Stonor v. Fowle* (13 App. Cas. 20); *The Bank of England v. Vagliano Brothers* (App. Cas. 1891). Upon his retirement in 1881, 26 judges and a huge gathering of the bar entertained him at a banquet in the Inner Temple hall. In December of the same year he was raised to the peerage. Politically he was a strong individualist and opposed to what he called "grandmotherly legislation," and sat in appeals to the House of Lords. Bramwell died on May 9, 1892.

His younger brother, Sir Frederick Bramwell (1818-1903), was a well-known consulting engineer and "expert witness."

**BRAN**, in Celtic legend, the name of (1) the hero of the Welsh *Mabinogi of Branwen*, who dies in the attempt to avenge his sister's wrongs; he is the son of Llyr (=the Irish sea-god Lir), identified with the Irish Bran mac Allait, Allait being a synonym

of Lir; (2) the son of Febal, known only through the 8th century Irish epic, *The Voyage of Bran* (to the world below); (3) the dog of Ossian's Fingal.

See Kuno Meyer and D. Nutt, *The Voyage of Bran* (1895).

**BRAN**, the broken outer coat of cereals, used as a feeding-stuff for cattle and horses, and for packing and other purposes. It is the ground husk of the grain. In the case of wheaten bran, the digestible matter in 1,000 lb. is as follows:—

|                              | lb. |
|------------------------------|-----|
| Nitrogenous substances ..... | 110 |
| Fat .....                    | 27  |
| Soluble Carbohydrates .....  | 426 |
| Fibre .....                  | 22  |
| Total organic matter .....   | 585 |

Thus, wheaten bran has a nitrogenous content about as great as wheat or oats and far more than good meadow hay.

**BRANCH**, a limb of a tree; hence any offshoot, e.g., of a river, railway, etc., of a deer's antlers, of a family or genealogical tree, or a subdivision or department, as in "a branch of learning" (Fr. *branche*, late Lat. *branca*, an animal's paw). The phrase, to destroy "root and branch," meaning to destroy utterly was made famous in 1641 by the so-called "Root and Branch" Bill (see CROMWELL, OLIVER; CLARENDON, 1ST EARL OF). Among technical senses of the word "branch" are the certificate of proficiency given to pilots by Trinity House and, in siege-craft, a length of trench forming part of a zigzag approach.

**BRANCHIOPODA**, one of the sub-classes of the Crustacea (*q.v.*), comprising some of the most primitive existing forms of the class, distinguished by the flattened, leaf-like form of the limbs. Although, like most Crustacea, they cannot be said to have any popular English names, various members of the group have been distinguished by writers on natural history as Fairy shrimps, Tadpole shrimps, Clam shrimps and Water fleas. Nearly all of them are inhabitants of fresh water, and they are remarkable for the prevalence of parthenogenesis (reproduction by unfertilized eggs) and for the fact that the eggs resist desiccation and can survive for long periods in the dry state. Owing to this they often make their appearance in numbers in rain-pools, even in dry countries where for long periods no aquatic life is possible.

The members of the five orders named below differ much in structure. Those of the first four orders are characterized by the large number of somites, the general uniformity of the trunk-limbs, and, in the living species, by the tubular form of the heart

FIG. 1.—MALE BRINE SHRIMP (*BRANCHINECTA PALUDOSA*), A MEMBER OF THE ANOSTRACA GROUP

It has a circumpolar distribution and occurs in stagnant, shallow pools. The claspers of the male are formed from the second pair of antennae

and the "ladder-like" arrangement of the central nervous system. These characters are very primitive, but on the other hand the palpless mandibles and the reduced maxillulae and maxillae are more specialized than those of some other Crustacea.

The *Anostraca* have no carapace and the fully segmented body is almost worm-like. The males are distinguished by the modification of the antennae into large and complicated claspers which are used for holding the females. The eyes are set on movable stalks. Most *Anostraca* inhabit rain-pools and other temporary accumulations of fresh water, but the "Brine-shrimp" (*Artemia*) is found in the brine of salt-pans in which sea-water is exposed to evaporation by the heat of the sun for the manufacture of salt,

and in salt lakes in which the brine is so concentrated that few other animals can live in it. Brine shrimps are found all over the world wherever conditions are suitable. Specimens from different localities differ considerably, but it has been shown that many of their variations are directly correlated with the degree of

FROM "PHILOS. TRANS." BY COURTESY OF THE ROYAL SOCIETY AND D. J. SCOURFIELD  
FIG. 2.—DEVONIAN FOSSIL (LEPIDOCARIS RHYNIENSIS), A MINUTE CRUSTACEAN KNOWN ONLY FROM FOSSIL REMAINS IN THE OLD RED SANDSTONE OF SCOTLAND  
The lower figure is a side view of the female. The upper figure shows the under side of the head of the male

salinity of the water and probably many of the forms described are variants of a single cosmopolitan species. The brine shrimps are the only *Anostraca* known to be parthenogenetic, some colonies consisting entirely of females.

Related to the *Anostraca* is the order *Lipostraca* established for the remarkable fossil *Lepidocaris* discovered in the old red sandstone of Scotland. The remains of this minute Crustacean although fragmentary are so perfectly preserved that its structure is known in greater detail than that of any other fossil Crustacean. Resembling the *Anostraca* in general form, it differs from them in the structure of the limbs, of which the posterior pairs are simply biramous; in the absence of paired eyes; and, most remarkably, in the claspers of the male which are formed, not by the antennae but by the maxillulae.

The *Notostraca* have a broad, shield-shaped carapace covering the fore part of the body and giving the animals, at first sight, some resemblance to the Arachnid King Crabs, with which, however, they have no near relationship. The somites and appendages are more numerous than in any other living Crustacea. The eyes are sessile on the upper surface of the head, and the antennules and antennae are much reduced, their place as "feelers" being perhaps taken by the filamentous terminal processes of the first pair of feet. The principal genus is *Apus* (*Triops*), the species of which may be two or even three inches long. Reproduction is largely parthenogenetic and males are rare.

FROM LANKESTER, "TREATISE ON ZOOLOGY"  
FIG. 3.—LEPIDURUS GLACIALIS  
Like most branchiopods, it is found in pools of water. When these dry up, the eggs remain buried in the mud at the bottom to hatch when rain fills up the pool again

The *Conchostraca* have the carapace in the form of a bivalve shell enclosing the body and limbs and marked with concentric "lines of growth," so that it resembles very closely the shell of a lamellibranch mollusc. The large two-branched antennae are used in swimming. The paired eyes are sessile and are more or less completely coalesced into one.

The *Cladocera* are closely related to the *Conchostraca*, from which they should not, perhaps, be separated as a distinct order, and from which they differ chiefly in the great reduction in the number of body-somites and of limbs. They are the "water fleas" which are abundant everywhere in ponds and lakes. All are of small size and some species which do not exceed one hundredth of an inch in length are among the smallest of living Crustacea. Their transparency, which allows the internal structure to be studied in the living animal, makes them interesting objects for microscopic examination. The *Cladocera* reproduce largely by parthenogenesis. The developing eggs are carried within the shell of the female. In addition to the parthenogenetic eggs, which hatch while still within the brood-chamber, the *Cladocera* produce, at certain seasons, another kind of eggs which require to be fertilized. These eggs have a thick shell and do not hatch at once but are cast off when the shell of the female is moulted and often a specially thickened part of the shell forms an additional protection. These "resting eggs" can survive drying or freezing without injury. They are often produced in autumn and do not hatch until the following spring; in species that live in

**BRANCO or PARIMA**, a river of northern Brazil and tributary of the Rio Negro, formed by the confluence of the Takutú, or "Upper Rio Branco," and Uraricoera, about 3° N. and 60° 28' W., and flowing south by west to a junction with the Negro. It has rapids in its upper course, but the greater part of its length of 348m. is navigable for steamers of light draught. The Takutú rises in the Roraima and Coirrit ranges on the Guiana frontier, while the Uraricoera rises in the Serra de Parima, on

the Venezuelan frontier, and has a length of 360m. before reaching the Branco. These are white water rivers, from which the Branco (white) derives its name, and at its junction with the Negro the two differently coloured streams flow side by side for some distance before mingling.

**BRANCOVAN or BRANCOVEANU**, the name of a family of Walachian hospodars which played an important part in the history of Rumania. It was of Serbian origin and was connected with the family of Branko or Brankovich. Constantine Brancovan, the most eminent member of the family, was born in 1654, and became hospodar of Walachia in 1689. In consequence of his anti-Turkish policy of forming an alliance first with Austria and then with Russia, he was denounced to the Porte, deposed from his throne, brought under arrest to Constantinople and imprisoned (1710) in the fortress of Yedi Kuleh (Seven Towers). Here he was tortured by the Turks, who hoped thus to discover the fortune of £3,000,000, which Constantine was alleged to have amassed. He was beheaded with his four sons on Aug. 26, 1714.

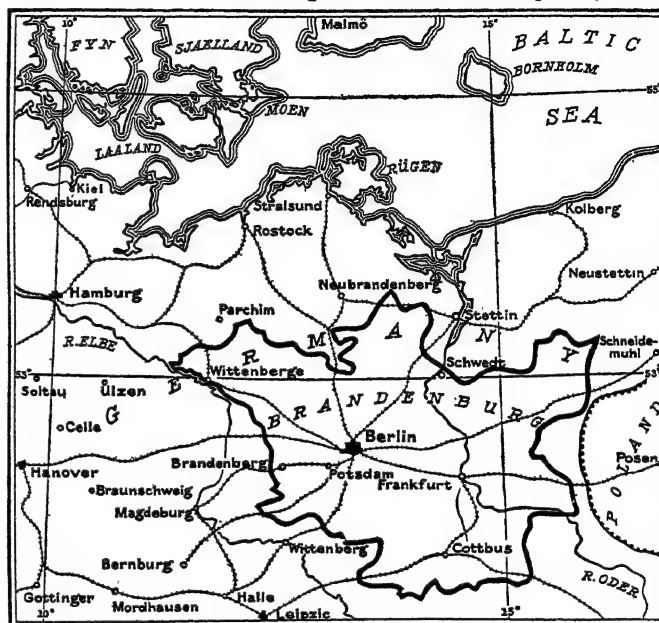

See N. Jorga, *Documents concernant le règne du prince Constantin Brâncoveanu* (1901).

**BRAND, SIR JOHN HENRY** (1823–1888), president of the Orange Free State, was the son of Sir Christoffel Brand, speaker of the House of Assembly of Cape Colony. He was born at Cape Town on Dec. 6, 1823, and was educated at the South African College in that city. Continuing his studies at Leyden, he took the degree of D.C.L. in 1845, was called to the English bar from the Inner Temple in 1849, and practised (1849–63) as an advocate in the supreme court of the Cape of Good Hope. In 1858 he was appointed professor of law in the South African College. He was elected president of the Orange Free State in 1863, and subsequently re-elected for five years in 1869, 1874, 1879 and 1884. In 1864 he resisted the pressure of the Basuto on the Free State boundary, and took up arms against them in 1865. This first war ended in the treaty of Thaba Bosigo, signed on April 3, 1866; and a second war ended in the treaty of Aliwal North, concluded on Feb. 12, 1869. In 1871 Brand was asked by a large party to become president of the Transvaal, and thus unite the two Dutch republics of South Africa; but as the project was hostile to Great Britain he declined to do so, and maintained his constant policy of friendship towards England. He received the G.C.M.G. in 1882. He died on July 14, 1888. (See ORANGE FREE STATE: *History*.)

**BRAND, JOHN** (1744–1806), English antiquary, was born on Aug. 19, 1744, at Washington, Durham, where his father was parish clerk. Educated at Newcastle grammar school and Lincoln college, Oxford, he took holy orders, and held various preferments, finally becoming rector of St. Mary-at-Hill and St. Mary Hubbard, London. He was for many years secretary to the society of antiquaries. His most important work is *Observations on Popular Antiquities: including the whole of Mr. Bourne's "Antiquitates Vulgares"* (1777). A new edition, embodying the mss. which he left when he died, was published by Sir Henry Ellis in 1813.

**BRANDEIS, LOUIS DEMBITZ** (1856– ), American jurist, was born in Louisville (Ky.) on Nov. 13, 1856. He was educated in the public schools of his native city and at the Annen Realschule, Dresden, Germany. He graduated from the Harvard law school in 1877, was admitted to the bar in 1878, and practised in Boston from 1879 to 1916. He was much interested in labour legislation, acting as counsel for the people in cases concerning the power of the government to fix hours of labour and a minimum wage in several states. In 1910 he was counsel in the Ballinger-Pinchot investigation in Congress; in 1910–11 was counsel for the shippers before the Interstate Commerce Commission in the advance freight-rate case; and in 1913–14 was special counsel for the commission in the second advance freight-rate case. In Jan. 1916 he was appointed by President Wilson associate justice of the Supreme Court, being the first Jew to attain this position. He was the author of *Other People's Money* (1914) and *Business as a Profession* (Boston, 1914), besides numerous articles on public franchise, business efficiency, Zionism, Jewish problems, labour and trusts.

**BRANDENBURG**, the name of a margraviate and electorate that later became the kingdom of Prussia. The district was inhabited by the Semnones, and afterwards by various Slavonic tribes, who were partially subdued by Charlemagne, but soon regained their independence. Later Henry the Fowler defeated the Havelli, or Hevelli, and took their capital, Brennibor, from which the name Brandenburg is derived. Subsequently Gero,

BASED ON A MAP IN THE COLLECTION OF THE ROYAL GEOGRAPHICAL SOCIETY  
MAP OF BRANDENBURG, THE SMALL MARGRAVIATE WHICH, UNDER THE HOHENZOLLERNS, DEVELOPED INTO THE KINGDOM OF PRUSSIA  
The Hohenzollern connection began in 1410. In 1415, Frederick of Hohenzollern was invested with the office of Elector of Brandenburg. In 1701 the title, King of Prussia, was secured by the Hohenzollerns and from this date the history of Brandenburg became merged in that of Prussia

margrave of the Saxon east mark, pressed the campaign against the Slavs with vigour, while Otto the Great founded bishoprics at Havelberg and Brandenburg. When Gero died in 965, his mark was divided into two parts, the northern portion, lying along both banks of the middle Elbe, being called the north or old mark, and forming the nucleus of the later margraviate of Brandenburg. After Otto the Great died, the Slavs regained much of their territory, including Brandenburg. A succession of feeble margraves ruled only the district west of the Elbe, together with a small district east of that river.

**Albert the Bear.**—A new era began in 1106 when Lothair, count of Supplinburg, became duke of Saxony. Aided by Albert the Bear, count of Ballenstädt, he renewed the attack on the Slavs, and in 1134 appointed Albert margrave of the north mark. About 1140, Albert made a treaty with Pribislaus, the childless duke of Brandenburg, by which he was recognized as the duke's heir, taking the title margrave of Brandenburg. Albert was the real founder of Brandenburg. Under his rule Christianity and civilization were extended, bishoprics were restored and monasteries founded, and the country colonized with settlers from the lower Rhineland.

When Albert died in 1170, Brandenburg fell to his eldest son, Otto I. (c. 1130–84), who compelled the duke of Pomerania to own his supremacy, and slightly increased by conquest the area of the mark. Otto's son and successor, Otto II., having quarrelled with Ludolf, archbishop of Magdeburg, was forced to own the archbishop's supremacy over his allodial lands. His successor, Albert II. (c. 1174–1220) assisted the emperor Otto IV., but later transferred his allegiance to Otto's rival, Frederick of Hohenstaufen, afterwards the emperor Frederick II. His sons, John I. and Otto III., ruled Brandenburg in common until the death of John in 1266, and their reign was a period of growth and prosperity. Districts were conquered or purchased from the surrounding dukes; the marriage of Otto with Beatrice, daughter of Wences-

laus, king of Bohemia, in 1253, added upper Lusatia to Brandenburg; and the authority of the margraves was extended beyond the Oder. Many monasteries and towns were founded, among them Berlin, and the prosperity of Brandenburg formed a marked contrast to the disorder which prevailed elsewhere in Germany. Brandenburg appears about this time to have fallen into three divisions—the old mark lying west of the Elbe, the middle mark between the Elbe and the Oder, and the new mark, as the newly conquered lands beyond the Oder began to be called. When Otto died in 1267, the area of the mark had been almost doubled, and the margraves had attained to an influential position in the Empire. The *Sachsenspiegel*, written before 1235, mentions the margrave as one of the electors, by virtue of the office of chamberlain, which had probably been conferred on Albert the Bear by the German king Conrad III.

In 1258 John and Otto had agreed upon a division of their lands, but the arrangement only took effect on Otto's death in 1267, when John's son, John II., received the electoral dignity, together with the southern part of the margraviate, which centred around Stendal, and Otto's son, John III., the northern or Saltzwedel portion. John II.'s brother, Otto IV., who became elector in 1281, had passed his early years in struggles with the archbishop of Magdeburg, whose lands stretched like a wedge into the heart of Brandenburg. Otto was succeeded in 1309 by his nephew, Valdemar, who conquered Pomerellen, which he shared with the Teutonic order in 1310, and held his own in a struggle with the kings of Poland, Sweden and Denmark and others, over the possession of Stralsund. By marriage, purchase or inheritance Valdemar finally came to rule over the whole mark, upper and lower Lusatia, and various outlying districts. He died childless in 1319, and was succeeded by his nephew Henry II., who died in 1320, when the Ascanian family, as the descendants of Albert the Bear were called, from the Latinized form of the name of their ancestral castle of Aschersleben, became extinct.

**Wittelsbach Dynasty.**—Brandenburg now fell into a deplorable condition, portions were seized by neighbouring princes, and various claimants disputed for the mark itself. In 1323 King Louis IV. took advantage of this condition to bestow the mark upon his young son, Louis, and thus Brandenburg was added to the possessions of the Wittelsbach family, although Louis did not receive the extensive lands of the Ascanian margraves. Upper and lower Lusatia, Landsberg, and the Saxon Palatinate had been inherited by female members of the family, and passed into the hands of other princes, the old mark was retained by Agnes, the widow of Valdemar, who was married again to Otto II., duke of Brunswick, and the king was forced to acknowledge these claims, and to cede districts to Mecklenburg and Bohemia. During the early years of the reign of Louis, who was called the margrave Louis IV. or V., Brandenburg was administered by Bertold, count of Henneberg, who established the authority of the Wittelsbachs in the middle mark, which, centring round Berlin, was the most important part of the margraviate. During the struggle between the families of Wittelsbach and Luxemburg, which began in 1342, there appeared in Brandenburg an old man who claimed to be the margrave Valdemar. He was gladly received by the king of Poland and other neighbouring princes, welcomed by a large number of the people, and in 1348 invested with the margraviate by King Charles IV. This step compelled Louis to make peace with Charles, who abandoned the false Valdemar, invested Louis and his step-brothers with Brandenburg, and in return was recognized as king. Louis recovered the old mark in 1348, drove his opponent from the land, and in 1350 made a treaty with his step-brothers, Louis the younger and Otto, at Frankfurt-on-Oder, by which Brandenburg was handed over to Louis the younger and Otto. Louis made peace with his neighbours, finally defeated the false Valdemar, and was recognized by the Golden Bull of 1356 as one of the seven electors. The emperor Charles IV. took advantage of a family quarrel over the possessions of Louis the elder, who died in 1361, to obtain a promise from Louis the younger and Otto, that the margraviate should come to his own son, Wenceslaus, in case the electors died childless. Louis the younger died in 1365, and when his brother Otto, who had married a daughter

of Charles IV., wished to leave Brandenburg to his own family Charles began hostilities; but in 1373 an arrangement was made, and Otto, by the treaty of Fürstenwalde, abandoned the margraviate for a sum of 500,000 gold gulden.

Under the Wittelsbach rule, the estates of the various provinces of Brandenburg had obtained the right to coin money, to build fortresses, to execute justice, and to form alliances with foreign states. Charles invested Wenceslaus with the margraviate in 1373, but undertook its administration himself, and passed much of his time at a castle which he built at Tangermünde. He diminished the burden of taxation, suppressed the violence of the nobles, improved navigation on the Elbe and Oder, and encouraged commerce by alliances with the Hanse towns, and in other ways. He caused a *Landbook* to be drawn up in 1375, in which are recorded all the castles, towns and villages of the land with their estates and incomes. When Charles died in 1378, and Wenceslaus became German and Bohemian king, Brandenburg passed to the new king's half-brother Sigismund, then a minor, and a period of disorder ensued. Soon after Sigismund came of age he pledged a part of Brandenburg to his cousin Jobst, margrave of Moravia, to whom in 1388 he pledged the remainder of the electorate in return for a large sum of money, and as the money was not repaid, Jobst obtained the investiture in 1397 from King Wenceslaus. Sigismund had also obtained the new mark on the death of his brother John in 1396, but sold this in 1402 to the Teutonic order. When, in 1410, Sigismund and Jobst were rivals for the German throne, Sigismund, anxious to obtain another vote in the electoral college, declared the bargain with Jobst void, and empowered Frederick VI. of Hohenzollern, burgrave of Nuremberg, to exercise the Brandenburg vote at the election. (*See* **FREDERICK I., ELECTOR OF BRANDENBURG.**) In 1411 Jobst died and Brandenburg reverted to Sigismund, who appointed Frederick as his representative to govern the margraviate. A further step was taken when, on April 30, 1415, the king invested Frederick of Hohenzollern and his heirs with Brandenburg, together with the electoral privilege and the office of chamberlain, in return for a payment of 400,000 gold gulden: the formal ceremony of investiture was delayed until April 18, 1417, when it took place at Constance.

Before the advent of the Hohenzollerns in Brandenburg its internal condition had become gradually worse and worse. The margraves were technically only the representatives of the emperor. But in the 13th century this restriction began to be forgotten, and Brandenburg enjoyed an independence and carried out an independent policy in a way that was not paralleled by any other German state. This independence was enhanced by the fact that there were few large lordships with their crowd of dependants. The towns, the village communities and the knights held their lands and derived their rights directly from the margraves. The towns and villages had generally been laid out by contractors or *locatores*, men not necessarily of noble birth, who were installed as hereditary chief magistrates of the communities, and received numerous encouragements to reclaim waste lands. This mode of colonization was especially favourable to the peasantry, who seem in Brandenburg to have retained the disposal of their persons and property at a time when villeinage or serfdom was the ordinary *status* of their class elsewhere. The dues paid by these contractors in return for the concessions formed the main source of the revenue of the margraves. Gradually, however, the expenses of warfare, liberal donations to the clergy, and the maintenance of numerous and expensive households, compelled them to pledge these dues for sums of ready money. The village magistrates came to be replaced by baronial nominees, and the peasants sank into a condition of servitude and lost their right of direct appeal to the margrave. Many of the towns were forced into the same position. Others were able to maintain their independence, and to make use of the pecuniary needs of the margraves to become practically municipal republics. In the embarrassments of the margraves also originated the power of the *Stände*, or estates, the nobles, the clergy and the towns. The first recorded instance of the *Stände* co-operating with the rulers occurred in 1170; but it was not till 1280 that the margrave solemnly bound himself not to raise a *bede* or special voluntary contribution without

the consent of the estates. In 1355 the *Stände* secured the appointment of a permanent councillor, without whose concurrence the decrees of the margraves were invalid. Anarchy had reigned for a century before the Hohenzollern rule began: upper and lower Lusatia, the new mark of Brandenburg, and other outlying districts had been shorn away and the electorate now consisted of the old mark, the middle mark with Priegnitz, Uckermark and Sternberg, a total area of not more than 10,000sq.m.

#### THE HOHENZOLLERNS

Such was the condition and extent of Brandenburg in 1411 when Frederick of Hohenzollern became margrave. Entering the electorate with a strong force in June 1412, it was not until 1417 that his authority over it was undisputed. His claim to suzerainty over Pomerania provoked an invasion of the mark by an army of Pomeranians with their allies in 1420, when Frederick inflicted a severe defeat upon them at Angermünde; but in 1424 a temporary coolness between the elector and the emperor Sigismund led to a renewal of the attack which Frederick was unable to repulse. This reverse, together with the pressure of other business, induced him to leave Brandenburg in Jan. 1426, after handing over its government to his eldest son, John, whose weak rule induced a renewed state of anarchy.

On Frederick's death in Sept. 1440 he was succeeded in the electorate by his eldest son Frederick II., surnamed "Iron" from the rigour of his government. Suppressing the rebellious nobles with ease, he found it less easy to deal with the towns. Three strong leagues had been formed among them about 1431, and the spirit of municipal independence was most prominently represented by the neighbouring and allied towns of Berlin and Cöln. In his conflict with the towns, the elector's task was lightened by a quarrel between the magistrates and the burghers of Berlin, which he was called in to decide in 1442. He deposed the governing oligarchy, changed the constitution of the town, forbade all alliances and laid the foundations of a castle. The inhabitants soon chafed under these restrictions. A revolt broke out in 1447, but the power of the elector overawed the people, who submitted their case to the estates, with the result that the arrangement of 1442 was re-established. In 1447 Frederick was compelled to cede the old mark and Priegnitz to his younger brother, Frederick, under whose feeble rule they quickly fell into disorder. In 1463, however, when the younger Frederick died childless, the elector united them again with his own possessions and took measures to suppress the prevailing anarchy. In his dealings with neighbouring rulers Frederick pursued a peaceful and conciliatory policy. In 1442 he obtained some small additions to his territory, and the right of succession to the duchy of Mecklenburg in case the ducal family should die out. In 1445 an old feud with the archbishop of Magdeburg was settled, and in 1457 a treaty of mutual succession was made with the houses of Saxony and Hesse. Cottbus and Peitz in Lusatia were acquired, and retained after a quarrel with George Podiebrad, king of Bohemia, and the new mark of Brandenburg was purchased from the Teutonic order in 1454. An attempt, however, to secure the duchy of Pomerania-Stettin failed, and the concluding years of his reign were troubled by warfare with the Pomeranians. Frederick's interest in ecclesiastical questions was mainly directed towards quickening the religious life of his people. He obtained important concessions from Pope Nicholas V. on the appointment of bishops and other ecclesiastical matters in 1447, and in general maintained cordial relations with the papacy. About 1467 his only son, John, died, and increasing infirmity led him to contemplate abdication. An arrangement was made with his brother, Albert Achilles, to whom early in 1470 the mark was handed over, and Frederick retired to Plassenburg where he died on Feb. 10, 1471.

**Dispositio Achillea.**—Albert took up the struggle with the Pomeranians, which he soon brought to a satisfactory conclusion; in May 1472 he not only obtained the cession of several districts, but was recognized as the suzerain of Pomerania and as its future ruler. The expenses of this war led to a quarrel with the estates. A subsidy was granted which the elector did

not regard as adequate, and by a dexterous use of his power he established his right to take an excise on beer. Albert's most important contribution to the history of Brandenburg was the issue on Feb. 24, 1473, of the *Dispositio Achillea*. By this instrument the elector decreed that the electoral mark should pass in its entirety to his eldest son, an establishment of primogeniture which had considerable influence on the future development of the country. He then entrusted the government to his eldest son, John, and left Brandenburg. Handicapped by poverty, John had to face attacks from two quarters. The Pomeranians, inspired by the declaration of the emperor Frederick III. that their land was a direct fief of the Empire, and aided by Matthias Corvinus, king of Hungary, took up arms; and a quarrel broke out with John, duke of Sagan, over the possessions of John's brother-in-law, Henry XI., duke of Glogau. To deal with these difficulties Albert returned to Brandenburg in 1478, and during his stay drove back the Pomeranians, and added Crossen and other parts of duke Henry's possessions to the electorate. Again left in charge of the country, John beat back a fresh attack made by John of Sagan in 1482; and he became elector on his father's death in March 1486. He added the county of Zossen to his possessions in 1490, and in 1493 made a fresh treaty with the duke of Pomerania. Although he brought a certain degree of order into the finances, his poverty and the constant inroads of external enemies prevented him from seriously improving the condition of the country. John welcomed Italian scholars to the electorate, and strove to improve the education of his people. He died at Arneburg on Jan. 9, 1499, and was succeeded by his son Joachim I.

When Joachim undertook the government of Brandenburg he found highway robbery general, the lives and property of traders in continual jeopardy, and the machinery for the enforcement of the laws almost at a standstill; but in a few years the execution of many lawbreakers and other stern measures restored some degree of order. Joachim proved himself a sincere friend to the towns by issuing sumptuary laws and encouraging manufactures; while to suppress the rivalry among the towns he established an order of precedence for them. He founded the university at Frankfort-on-Oder in 1506, and he gave a new organization to the highest court of justice, the *Kammergericht*, secured for himself an important voice in the choice of its members, and ordered that the local law should be supplemented by the law of Rome. He did not largely increase the area of Brandenburg, but in 1524 he acquired the county of Ruppin, and in 1529 made a treaty at Grimnitz with George and Barnim XI., dukes of Pomerania, by which he surrendered the vexatious claim to suzerainty in return for a fresh promise of the succession in case the ducal family should become extinct. Joachim's attitude towards the teaching of Martin Luther, which had already won many adherents in the electorate, was one of unrelenting hostility. The Jews also felt the weight of his displeasure, and were banished in 1510.

**The Reformation.**—Ignoring the *Dispositio Achillea*, the elector bequeathed Brandenburg to his two sons. When he died in July 1535 the elder, Joachim II., became elector, and obtained the old and middle marks, while the younger, John, received the new mark. John went definitely over to the side of the Lutherans in 1538, while Joachim allowed the reformed doctrines free entrance into his dominions in 1539. The elector, however, unlike his brother, did not break with the forms of the Church of Rome, but established an ecclesiastical organization independent of the pope, and took up a position similar to that of King Henry VIII. in England. Many of the monasteries were suppressed, and a consistory set up to take over the functions of the bishops and to act as the highest ecclesiastical court of the country. In 1541 the new ecclesiastical system was confirmed by the emperor Charles V. Doubtless the elector was influenced religiously by considerations of greed. The bishoprics of Brandenburg, Havelberg and Lebus were secularized; their administration was entrusted to members of the elector's family; and their revenues formed a welcome addition to his impoverished exchequer. Nor did Joachim neglect other opportunities for adding

to his wealth and possessions. In 1537 he had concluded a treaty with Frederick III., duke of Liegnitz, which guaranteed to the Hohenzollerns the succession to the Silesian duchies of Liegnitz, Brieg and Wohlau in the event of the ducal family becoming extinct; this arrangement is important as the basis of the claim made by Frederick the Great on Silesia in 1740. The treaty was declared invalid by the German king, Ferdinand I.; but the elector insisted on its legality, and in 1545 strengthened his position by arranging a double marriage between members of his own family and that of Duke Frederick. Of more immediate consequence was an arrangement made in 1569 with the representatives of Joachim's kinsman, Albert Frederick, duke of Prussia, after which the elector obtained the joint investiture of the duchy of Prussia from Sigismund II., king of Poland, and was assured of the succession if the duke's family became extinct. Joachim's extravagance compelled him in 1540 to appeal for help to the estates. The estates voted him a sum of money as the price of valuable concessions, the most important of which was that the elector should make no alliance without their consent. Fresh liabilities were soon incurred, and in spite of frequent contributions from the estates Joachim left at his death in Jan. 1571 a heavy burden of debt to his son and successor, John George.

The elector's death was followed ten days later by that of his brother, John, and as John left no sons the whole of Brandenburg, together with the districts of Beeskow and Storkow which had been added by purchase to the new mark, were united under the rule of his nephew, John George. The rule of John George was popular with the nobles, and to some extent with the towns. His financial reforms and wise government greatly benefited Brandenburg. Although by faith a Lutheran he did not allow his religious tenets to involve his state in military adventures in defence of the Protestant cause. He died on Jan. 8, 1598.

Ignoring the *Depositio Achillea*, he left his dominions to a younger son, Joachim Frederick, born on Jan. 27, 1546, who now became elector. Since 1553 he had held the bishopric of Havelberg, since 1555 that of Lebus; he had been administrator of Magdeburg since 1566, and of Brandenburg since 1571. Resigning these dignities in 1598, he contested his father's will, and was successful in preventing a division of the electorate. An agreement with George Frederick, the childless margrave of Ansbach and Bayreuth, paved the way for an arrangement with the elector's younger brothers, who after the margrave's death in April 1603, shared his lands in Franconia, and were compensated in other ways for surrendering all claims on Brandenburg. This agreement, known as the Gera Bond, ratified the *Dispositio Achillea*. By George Frederick's death, Joachim became administrator of the duchy of Prussia, ruled nominally by the weak-minded Albert Frederick, but he had some difficulty in asserting his position. In Brandenburg he made concessions to the nobles at the expense of the peasantry, and admitted the right of the estates to control taxation. In religious matters he was convinced of the necessity of a union between Lutherans and Calvinists, and took steps to bring this about. Public opinion, however, in Brandenburg was too strong for him, and he was compelled to fall back upon the Lutheran *Formula* and the religious policy of his father. Joachim seems to have been a wise ruler, who improved in various ways the condition of the mark. He married Catherine, daughter of John, margrave of Brandenburg-Cüstrin, and when he died, on July 18, 1608, was succeeded by his eldest son John Sigismund.

The new elector, born on Nov. 8, 1572, had married in 1594 Anna, daughter of Albert Frederick of Prussia, a union which not only strengthened the pretensions of the electors of Brandenburg to the succession in that duchy, but gave to John Sigismund a claim on the duchies of Cleves, Jülich and Berg, and other Rhenish lands should the ruling family become extinct. In March 1609 the death of Duke John William left these duchies without a ruler, and by arrangement they were occupied jointly by the elector and by his principal rival, Wolfgang, son of Philip Louis, count palatine of Neuburg. This proceeding aroused some opposition, and, complicated by religious considerations and by the excited state of European politics, almost precipitated a general

war. However, in Nov. 1614 the dispute was temporarily settled by the treaty of Xanten. Brandenburg obtained the duchy of Cleves with the counties of Mark and Ravensberg, but as the Dutch and Spanish garrisons were not withdrawn, these lands were only nominally under the elector's rule. In 1609, John Sigismund had joined the Evangelical Union, probably to win support in the Rhineland, and the same consideration was doubtless one reason why in 1613, he forsook the Lutheran doctrines of his family, and became an adherent of the reformed, or Calvinist faith. This step aroused grave discontent in the electorate, and, quickly abandoning his attempts to proselytize, the elector practically conceded religious liberty to his subjects. Over the Cleves-Jülich succession, John Sigismund had incurred heavy expenses, and the public debt had again mounted up. He was thus obliged to seek aid from the estates, and in return for grants to make concessions to the nobles. The elector spent much of his time in Prussia striving to assert his authority in that duchy, and in Aug. 1618, according to the arrangement of 1569, became duke by the death of Albert Frederick. He only enjoyed this dignity for a short time, as he died on Dec. 23, 1619. He was succeeded by his eldest son, George William, brother-in-law of Gustavus Adolphus of Sweden.

**The Thirty Years' War.**—The new elector, born on Nov. 3, 1597, proved a weak and incapable ruler. He had married Elizabeth, daughter of Frederick IV., elector palatine of the Rhine, and sister of the elector Frederick V., afterwards king of Bohemia, and before his accession had acted as his father's representative in Cleves. Although a Protestant he was under the influence of Adam, count of Schwarzenberg, who was a Roman Catholic of imperialist sympathies. As a result the elector remained neutral during the early years of the Thirty Years' War in spite of his relationship with Frederick of the Palatinate, and the obvious danger to his Rhenish lands. The attitude was not successful. Brandenburg was ravaged impartially by both parties, and in 1627 George William attacked his brother-in-law, Gustavus Adolphus of Sweden, who was using Prussia as a base of operations for his war against Poland. This campaign was short and inglorious for Brandenburg, and the elector was soon compelled to make peace. Although alarmed by the edict of restitution of 1629, George William took no steps to help the Protestants. In 1631, however, Gustavus Adolphus marched on Berlin, compelled the elector to cede the fortress of Spandau, and to aid him with men and money. The Brandenburg troops then assisted the Swedes until after the death of Gustavus in 1632, and the Swedish defeat at Nördlingen in 1634, when the elector assented to the treaty of Prague, which was made in May 1635 between the emperor Ferdinand II. and John George I., elector of Saxony. The imperialists did nothing, however, to drive the Swedes from Brandenburg. This was the principal reason why the elector was unable to annex Pomerania when its last duke, Bogislaus XIV., died in 1637. In 1638 George William transferred his residence to Königsberg, leaving Schwarzenberg to administer the electorate. Although his harsh measures aroused some irritation, the count did something to rid the land of the Swedes and to mitigate its many evils; but its condition was still very deplorable when George William died at Königsberg on Dec. 1, 1640, leaving an only son, Frederick William. The most important facts in the internal history of Brandenburg during the 16th century were the growth of the power of the estates, the gradual decline in the political importance of the towns, and the lapse of the peasantry into servitude. These events increased the power of the nobles, but circumstances were silently preparing the way for a great increase of authority on the part of the ruler. The substitution of the elector for the pope as head of the church; the introduction of Roman law with its emphasis on a central authority and a central administration; the determined and successful efforts to avoid any partition of the electorate; and the increasing tendency of the separate sections of the diet to act independently, all tended in this direction. This new order was heralded in 1604 by the establishment of a council of state, devoted to the interests of the elector, which strengthened his authority, and paved the way for a bureaucratic government.

## THE GREAT ELECTOR

When Frederick William, the "Great Elector," became ruler of Brandenburg in 1640 he found the country in a very deplorable condition. His first task was to restore order and in this he was eminently successful. He freed Brandenburg of the Swedes, and in 1647 secured his title to Cleves, Mark and Ravensberg.

The terms of the Treaty of Westphalia in 1648 are the best commentary on the general success of the elector's policy. Although he was obliged to give up his claim to the western part of Pomerania in favour of Sweden, he secured the eastern part of that duchy, together with the secularized bishoprics of Halberstadt, Minden and Kammin, and other lands, the whole forming a welcome addition to the area of Brandenburg. He was also promised the archbishopric of Magdeburg when its administrator, Augustus, duke of Saxe-Weissenfels, should die. This event happened in 1680 when he secured the lands of the archbishopric.

In his internal reforms, the elector sought to strengthen the central authority, and to mitigate the constant lack of money, which was perhaps his chief obstacle to success; a work in which he was aided by George, count of Waldeck (1620-92), who became his chief adviser about this time. He extended the powers of the state council. In foreign policy, he sought to promote an alliance against the Hapsburgs, and at first supported Louis XIV. of France. Becoming aware of the danger to Prussia from the aggressive policy of Louis, Frederick William allied himself with the Empire in 1674; but the humiliating terms of the Treaty of St. Germain-en-Laye, by which Brandenburg was forced to restore western Pomerania to Sweden, caused him to renew the French alliance in 1678 and 1681. Four years later, however, he was incensed by the anti-Protestant policy of Louis XIV., and allied himself with William of Orange.

The great elector died in May 1688. In 1640 the greater part of his territory was occupied by strangers and devastated by war. Brandenburg was merely an appendage of the Empire. Its army was useless; its soil was poor; its revenue was insignificant. At his death the state of Brandenburg-Prussia was inferior to Austria alone among the states of the Empire; it was regarded as the head of German Protestantism; while the fact that one-third of its territory lay outside the Empire added to its importance. Its area had been increased to over 40,000 sq. m.; its revenue had multiplied sevenfold; and its small army was unsurpassed for efficiency. The elector had overthrown Sweden and inherited her position on the Baltic, and had offered a steady and not ineffectual resistance to the ambition of France.

While thus winning for himself a position in the councils of Europe, Frederick William was not less active in strengthening the central authority within his own dominions. He found Brandenburg a constitutional state, in which the legislative power was shared between the elector and the diet; he left it to his successor substantially an absolute monarchy. Many circumstances assisted to bring about this change, among the chief of which were the want of harmonious action on the part of the estates, and the decline in the political power of the towns. The substitution of a permanent excise for the subsidies granted from time to time by the estates also tended to increase his independence, and the officials or *Steuerräthe*, appointed by him to collect this tax in the towns, gradually absorbed many of the administrative functions of the local authorities. The nobles and prelates generally preferred to raise their share of the revenue by the old method of a *bede*, or contribution, thus weakening the remaining bond between them and the burghers.

Education was not neglected, a trading company was established, and colonies were founded on the west coast of Africa. In religious matters Calvinists and Lutherans were placed upon an equality, but the elector was unable to impress his own spirit of tolerance upon the clergy, who were occupied with ecclesiastical squabbles while the state of education and of public morals left much to be desired. The condition of the peasantry, however, during his reign reached its lowest point, and the "recess," or charter, of 1653 practically recognized the existence of villeinage. The nobles had compensated themselves at the expense of the

peasants for the powers lost to the ruler. The Thirty Years' War afforded them frequent opportunities of replacing the village *Schulzen*, or magistrates, with officials of their own; and the fact that their share of taxation was wholly wrung from the peasants made the burden of the latter much heavier than that of the townsmen.

**The Kingdom of Prussia.**—The new elector, Frederick III., followed in general the policy of his father. Having persuaded his step-brothers to surrender the principalities bequeathed to them by the great elector, he assisted William of Orange to make his descent on England, in 1688 allied himself with other German princes against Louis XIV., and afterwards fought for the Empire against both France and Turkey. Frederick's chief adviser about this time was Eberhard Danckelmann (1643-1722), whose services in continuing the reforming work of the great elector were very valuable; but having made many enemies, the electress Sophia among them, he fell from power in 1697, and was imprisoned for several years. The most important work of the elector was to crown the labours of his father by securing the kingly title for himself and his descendants. Broached in 1692 this matter was brought up again in 1698 when the emperor and his ministers, faced with the prospect of a fight over the Spanish succession, were anxious to conciliate Brandenburg. It was at length decided that the title should be taken from Prussia rather than from Brandenburg as the former country lay outside the Empire, and in return Frederick promised to assist Leopold with 8,000 men. The coronation ceremony took place at Königsberg on Jan. 18, 1701. The territorial additions to Brandenburg during this reign were few and unimportant, but the comparative wealth and prosperity enabled the elector to do a good deal for education and to spend some money on buildings. In 1694 the university of Halle was founded; academies for arts and sciences were established, and Berlin was greatly improved. The subsequent history of Brandenburg is merged in that of Prussia (*q.v.*).

Koser, *Forschungen zur brandenburgischen und preussischen Geschichte* (Leipzig, 1888 fol.); J. Heidemann, *Die Reformation in der Mark Brandenburg* (1889); E. Berner, *Geschichte des preussischen Staats* (1890-91); B. Gebhardt, *Handbuch der deutschen Geschichte*, Band ii. (1901); R. Wolff, *Politik des Hauses Brandenburg* (1919); G. Küntzel, *Die drei grossen Hohenzollern* (Stuttgart, 1922).

**BRANDENBURG**, the central and largest province of the republic of Prussia, largely the former electorate of Brandenburg. It was merged in 1701 in the kingdom of Prussia and became one of the provinces of Prussia in 1815. It has an area of 15,072 sq. m. (or 15,411 sq. m., with the province of Berlin). Pop., without Berlin (1925) 2,611,432. The province is a sandy plain interspersed with numerous fertile districts and stretches of pine and fir woods. It was formerly popularly known as the "sandbox of the Holy Roman Empire." It is, however, well watered by the Elbe and the Oder and tributaries, and is besides remarkable for its lakes, numbering between 600 and 700. The mineral products comprise lignite, limestone, gypsum, alum and potter's earth; barley and rye are the usual cereals; fruits and vegetables are abundant; and hemp, flax, hops and tobacco are raised. Sheep-breeding is important, and wool is exported. The climate is characteristically "continental"—cold and raw in winter, excessively hot in summer. The most important industries are spinning and weaving (wool and cotton), paper-making and brandy distillation.

**BRANDENBURG**, a town of Prussia, Germany, capital of the district and province of Brandenburg, on the river Havel, 36 m. W. by S. of Berlin. Pop. (1925), 59,271. The town is enclosed by walls, and is divided into three parts by the river—the old town on the right and the new town on the left bank, with the "cathedral town" on an island between them. Many of the houses are built on piles in the river. "Old" and "new" Brandenburg were for

centuries separate, but came under a single municipality in 1717. Brandenburg, Brennaburg (Brennabor) or Brendanburg, was originally a town of the Slavic tribe of the Hevelli, from whom it was captured (927-928) by the German king Henry I. In 948, Otto I. founded a bishopric here, which was subordinated first to the archdiocese of Mainz, but from 968 onwards to the newly-created archbishopric of Magdeburg. It was destroyed by the Wends in 983, but was restored when Albert the Bear recaptured the town in 1153. In 1539, the bishop became Lutheran, and in 1598 the see was incorporated in the electoral domains. The cathedral chapter, however, survived.

The Katharinenkirche (14th-16th centuries) is a Gothic brick church with a fine carved wooden altar and several interesting mediaeval tombs. The cathedral (Domkirche), originally a Romanesque basilica (1170), but rebuilt in the Gothic style in the 14th century, has a good altar-piece (1465), and is noted for its remarkable collection of mediaeval vestments. Other churches are the Petrikirche (14th century), the Gothardskirche, partly Romanesque (1160), partly Gothic (1348), and the Nikolaikirche (12th and 13th centuries), now no longer used. The former town hall of the "old town" (Altstadt Rathaus), built in the 13th and 14th centuries, is now used as government offices. In front of the town hall in the Neustadt, in the market-place, stands a *Rolandssäule*, a colossal figure 18ft. in height, hewn out of a single block of stone. To the north of the town is the Marienburg, with a convent. The industries of Brandenburg include some metal-work, tin-plate products and bicycles, and woollen and jute goods.

**BRANDER, GUSTAVUS** (1720-1787), English naturalist, who came of a Swedish family, was born in London and became a director of the Bank of England. At his country residence at Christchurch in Hampshire he became interested in the fossils so abundant in the clays of Hordwell and Barton. A set of these, presented by him to the British Museum, was described by D. C. Solander in the beautifully illustrated work entitled *Fossilia Hantoniensia collecta, et in Museo Britannico deposita a Gustavo Brander* (1766). Brander was elected F.R.S. in 1754, and he was also a trustee of the British Museum.

**BRANDES, GEORG MORRIS COHEN** (1842-1927), Danish critic and literary historian, was born in Copenhagen, the son of a Jewish merchant. After graduating from the university of his native town, Brandes travelled much in Europe, publishing in 1868 his *Aesthetic Studies* on Danish poets. In 1871 he became reader in Belles Lettres at the University of Copenhagen, and although he was the obvious person for the professorship of aesthetics which became vacant in 1872, he was not elected because his modernism and championing of self-determination had offended many. He was known to be a Jew, he was convicted of being a Radical, and he was suspected of being an atheist.

Brandes now issued his *Main Streams of Literature in the 19th Century*, 4 vols. (1872-75), in which he describes the revolt against the pseudo-classicism of the 18th century. The work has been translated into the principal European languages, and has become a classic. From 1877 to 1883, while living in Berlin, he published *Danish Poets* (1877), *Ferdinand Lassalle* (1877), *Benjamin Disraeli* (1878) and *Men of the Modern Transition* (1883). In 1897 appeared his famous study of Shakespeare (Eng. trans. by W. Archer) and two years later his *Henrik Ibsen*. In 1902 his brilliant and lucid critical work outweighed prejudice, and he received the professorship of aesthetics at Copenhagen which had been denied him 30 years before.

During the World War Brandes sought to be impartial, but he openly quarrelled with his friend Clemenceau and displeased the Allies by his criticism of their colonial policy, and by his faith in post-Revolutionary Russia. He died on Feb. 19, 1927. The reaction against the naturalism of Brandes was started as early as 1885 by Holger Drachmann. (See DENMARK: Literature.)

Since the first collected edition of his works was published in 1900, some of his best-known books have appeared. These include: *Anatole France* (1905), *Life of Goethe* (1914), *Frederick Nietzsche* (Eng. trans. 1914), *Life of Voltaire* (1916), *The World War* (1916), *Julius Caesar* (1918), *Michael Angelo* (1921), *Hein-*

*rich Heine* (1922), *Creative Spirits of the 19th Century* (1924), *The Jesus Myth* (1925) and *Hellas* (1925).

His brother, EDVARD BRANDES (b. 1847), also a well-known critic, was the author of a number of plays and of two psychological novels: *A Politician* (1889) and *Young Blood* (1899).

**BRANDING**, in criminal law a mode of punishment; also a method of marking goods or animals; in either case by stamping with a hot iron. The Greeks branded their slaves with a Delta, Δ, for Δούλος. Robbers and runaway slaves were marked by the Romans with the letter "F" (*fur, fugitivus*); and the toilers in the mines, and convicts condemned to figure in gladiatorial shows, were branded on the forehead for identification. Under Constantine the face was not permitted to be so disfigured, the branding being on the hand, arm or calf. The canon law sanctioned the punishment, and in France galley-slaves could be branded "TF" (*travaux forcés*) until 1832. In Germany, however, branding was illegal. The punishment was adopted by the Anglo-Saxons, and the ancient law of England authorized the penalty. By the Statute of Vagabonds (1547) under Edward VI. vagabonds, gipsies and brawlers were ordered to be branded, the first two with a large "V" on the breast, the last with "F" for "fraymaker." Slaves, too, who ran away were branded with "S" on cheek or forehead. This law was repealed in 1636. From the time of Henry VII. branding was inflicted for all offences which received benefit of clergy (*q.v.*), but it was abolished for such in 1822. In 1698 it was enacted that those convicted of petty theft or larceny, who were entitled to benefit of clergy, should be "burnt in the most visible part of the left cheek, nearest the nose." This special ordinance was repealed in 1707.

Cold branding or branding with cold irons became in the 18th century the mode of nominally inflicting the punishment on prisoners of higher rank. Such cases led to branding becoming obsolete, and it was abolished in 1829 except in the case of deserters from the army. These were marked with the letter "D," not with hot irons but by tattooing with ink or gunpowder. Notoriously bad soldiers were also branded with "BC" (bad character). By the British Mutiny Act of 1858 it was enacted that the court martial, in addition to any other penalty, may order deserters to be marked on the left side, 2in. below the armpit, with the letter "D," such letter to be not less than 1in. long. In 1879 this was abolished. (See also MUTILATION.)

See W. Andrews, *Old Time Punishments* (Hull, 1890); A. M. Earle, *Curious Punishments of Bygone Days* (1896).

**BRANDIS, CHRISTIAN AUGUST** (1790-1867), German philologist and historian of philosophy, was born at Hildesheim, and graduated at Copenhagen. In 1816 he was secretary to the Prussian embassy at Rome, and later he assisted I. Bekker in his edition of Aristotle. In 1821 he became professor of philosophy at Bonn, and in 1823 published his *Aristotelius et Theophrasti Metaphysica*. His most important work is the *Handbuch der Geschichte der griechisch-röm. Philos.* (1835-66; republished in a smaller and more systematic form, *Gesch. d. Entwicklungen d. griech. Philos.* 1862-66). Brandis died on July 21, 1867.

See Trendelenburg, *Zur Erinnerung an C.A.B.* (1868).

**BRANDL, ALOIS** (1855- ), Austrian scholar, was born at Innsbruck, Austria, June 21 1855. He was successively professor of English literature at Prague, Goettingen, Strasbourg and Berlin. He was president of the German Shakespeare Society and from 1899 to 1918 joint editor of its *Jahrbuch*. He edited the reissue of the Tieck translation of Shakespeare (1897).

Brandl's chief works are: *Thomas of Erceadoun* (1881); *S. T. Coleridge und die englische Romantik* (1886); *Geschichte der alt-englischen Literatur und die englische Volksdichtung* (1892-1908); *W. Shakespeare* (1894); *Quellen des weltlichen Dramas in England vor Shakespeare* (1898); and the valuable *Geographie der alt-englischen Dialekte* (1915).

**BRANDON**, market town, West Suffolk, England, on the Little Ouse or Brandon river, 8½m. N.N.E. of London by the L.N.E. railway. Pop. of parish (1931) 5,768. Extensive deposits of flint are worked in the neighbourhood, and the work of the "flint-knappers" has had its counterpart here from early times. Close to Brandon, but in Norfolk across the river, at the village of Weeting, are the so-called Grimes' Graves, which are neolithic

flint workings. The pits were sunk through the overlying chalk to the depth of 20 to 60 ft., and numbered 254 in all. Passages branched out from them, and, among other remains, picks of deer-horn were discovered. The town has an Early English church and a 17th-century grammar school. There is some carrying trade by the Little Ouse.

**BRANDON**, the second largest city of Manitoba, on the Assiniboine 133m. W. of Winnipeg. Pop. (1931), 17,082. It was originally a trading post, is served by C.N.R. and C.P.R., and stands in a rich agricultural area. It has grain mills, brick works, creameries, etc., and is the seat of an important live-stock winter fair.

**BRANDS** are identification marks of products sold in trade. Their primary purposes are (1) to give buyers confidence in the articles they purchase, (2) to attach to the producer responsibility for his products and (3) to assist producers in advertising their products. There are four chief classes of brands: (1) trade marks; (2) private brands; (3) store labels; (4) copyrights. (1) Trade marks (*q.v.*) are identification marks used by manufacturers. They may be emblems, pictures, diagrams, words, or other ingenious devices. They are usually protected by statute and registered by a government bureau. (2) Private brands are similar to trade marks but they are usually owned by wholesalers or other large distributors. The private brand may also be registered in a number of the leading commercial countries but such use usually depends upon the common law for protection. The private brand is placed upon goods which a wholesaler or jobber buys for distribution. These goods may be made to his order and according to his specifications or they may be bought in the open market. (3) Store labels are applied to goods of some particular store or chain of stores. As with private brands, these goods may be bought in the open market or made to the order of the merchant. (4) Copyright (*q.v.*) applies to a particular class of labels, especially to those used by industrial or commercial associations; *e.g.*, the slogan "Save the Surface and You Save All" with the brush mark, is copyright in the United States. Members of the association which owns the copyright are permitted to use it in their advertising under restricted conditions. This use of the copyright is entirely different from its ordinary use, which is to protect works of art, books, music, etc.

While most of the present legislation pertaining to brands is of recent origin, and while the practice of placing a brand on the article has been greatly stimulated in the last quarter century, the brand idea is as old as any known institution of civilization. It marked the beginning of a philosophy in business by which the producer openly assumed a responsibility for his product to the purchaser. Through all the ages this system has stood out in striking contrast with the well-known *caveat emptor* doctrine, which implied that profit could be derived only by an equal loss to the other party to the transaction. From a legal standpoint, the consumer is protected by the brand as well as the manufacturer.

The earliest excavations showed that paving brick bore the mark of the manufacturer and also, in many instances, the mark of the slave who actually produced it. This is the same idea that still prevails with our use of the trade mark. The brick manufacturer wanted credit for his worthy product; he also wanted to hold each slave responsible for his output and the mark was valuable to him in placing responsibility. During the period when the guilds of Europe were active, the use of the brand was very highly developed and some of the legislation governing the use of identification marks was as highly perfected and as intelligently employed as in modern commerce. Infringers, however, were harshly treated. In the textile industry the punishment for infringements was to have the right hand of the infringer severed. Infringing the brand of Rudesheimer wine by substitution of an inferior article was punishable by death. There was one aspect of the guilds' practice that has never been applied in recent times. That was a penalty for the failure of a member of the guild to affix the guild's identification mark to all his products. With the disappearance of the guilds from commerce the use of brands greatly declined and it was not until 1875 that Great Britain enacted its basic trade-mark law; 30 years later a similar statute was adopted in the United States.

In the last half century it has become the common practice to brand even the most staple manufactured products. (H. E. A.)

**BRANDY**, an alcoholic potable spirit distilled from fermented grape juice. The term is often regarded as having the same application as the German "Branntwein" or the French "brandevin." This is not correct, as in France and Germany the respective titles are applied to any spirit obtained by distillation, the significance of the word being in the first syllable "brand" meaning burnt or burning. In France, also, brandy is known as Eau de Vie, a title which is applied equally and with legal authority to spirit distilled from wine, cider, perry, cherries, plums and "marc." It is evident also that at one time the term "brandy" or "brandy wine" had a similarly wide significance in England. Thus the preamble to an act passed in 1690 in the reign of William and Mary runs, "Whereas good and wholesome brandies, aqua vitae, and spirits may be drawn and made from malted corn, etc.," and as late as 1860 the Spirits act of that year prescribed that "all spirits which shall have had any flavour communicated thereto and all liquors whatsoever which shall be mixed or mingled with any such spirits shall be deemed a British compound called 'British brandy'." This section was repealed in 1880 and during the past half century the accepted sense of the term has been restricted to spirits obtained by distillation from fermented grape juice.

The definitions in the pharmacopoeia are of interest. Thus that of the United States for 1926 describes "Spiritus Vini Vitis" as "an alcoholic liquid obtained by the distillation of the fermented juice of sound, ripe grapes and containing not less than 54% by volume of  $C_2H_5OH$  at 15.56°C. It must have been stored in wood containers for a period of not less than four years." It is "a pale amber colored liquid, having a characteristic odour and taste and an acid reaction. Specific gravity from 0.933 to 0.941 at 25°C."

The British Pharmaceutical Codex (1923) under the title "Spiritus Vini Gallici" states that "brandy is obtained by distillation from the wine of grapes, and matured by age. It occurs as a pale amber coloured liquid, having a characteristic odour and taste and, as a rule, a slightly acid reaction. Specific gravity about 0.957. It contains about 40% by volume of ethyl hydroxide. It contains minute quantities of volatile acid, aldehydes, furfural, esters and higher alcohols, to which impurities or secondary products the characteristic flavour and odour are due."

Commercial brandy, however, does not correspond exactly with these definitions. As distilled it is a colourless liquid, but storage in casks, necessary to allow the spirit to mature, results in the extraction of certain materials from the wood imparting a pale brown colour to the liquid. This colouration varies with each cask and, for purposes of commercial standardization, a varying amount of caramel is added to bring the colour up to a uniform tint.

The brandies which enjoy the greatest popular favour are those from the Cognac district and the extension of the name to include the word Cognac, *e.g.*, "Eau de Vie de Cognac," under the French law can be applied only to spirits so derived. Brandy is manufactured in other districts of France such as Armagnac, Marmande, Nantes and Anjou, the spirit of poorest quality being known as Trois-Six de Montpellier.

It is of interest that, according to Beckmann, brandy is said to have been introduced into France from Italy in 1533 on the occasion of the marriage of Henry II., then Duke of Orleans, to Catherine de Medici. At the present time production in Italy is comparatively negligible. In other wine producing countries such as Spain and Algiers brandy is manufactured, the Spanish product being of high quality and resembling the French. In Australia and South Africa production is steadily increasing, although very little brandy is exported.

Another spirit for which the title Brandy is claimed is that obtained from the marc—the grape skins and other residue of the wine press. Although possessing characteristics of its own, Marc or "Dop" brandy, as it is called in South Africa, is generally accepted and is often of good quality.

The manufacture and importation of brandy in the United States is now prohibited except for medical and other non-beverage pur-

poses. In consequence there has been a marked decrease in the quantity imported, the figures, for example, for 1924 and 1925 respectively being 4,125 and 4,236 gallons, as compared with 510,725 in 1914.

In Great Britain and Northern Ireland also there is considerable decrease in the demand, the number of proof gallons retained for consumption during the past five years being as follows:

|         |         |
|---------|---------|
| 1922-23 | 666,089 |
| 1923-24 | 698,504 |
| 1924-25 | 653,144 |
| 1925-26 | 635,942 |
| 1926-27 | 554,484 |

These figures can be compared with those for the years 1913-14 (1,544,153) and 1921-22 (795,694), both of which, however, included the whole of Ireland. Although doubtless this decrease is due partly to alteration in the popular taste, it may also be ascribed in some measure to the increase in duty, which in 1914 was 15s. 1d. per proof gallon in cask and in 1928 is £3. 15s. 4d. full duty and £3. 12s. 10d. on spirit imported from British Dominions.

**Composition.**—In common with other potable spirits, brandy owes its flavour and aroma to the presence of small quantities of secondary ingredients. These are dissolved in the ethyl alcohol and water which form over 99% of the spirit. The results of the analysis of five samples of genuine Cognac brandy supplied to the Royal Commission of 1909 by Dr. P. Schidrowitz were as follows:—

| Age, etc.                                     | Grammes per 100 litres of absolute alcohol. |             |                    |         |                  |           |           |
|---|---|-------------|--------------------|---------|------------------|-----------|-----------|
|   | Alcohol % by volume.                        | Total acid. | Non-volatile acid. | Esters. | Higher alcohols. | Aldehyde. | Furfural. |
| 1. New, 1904 . . . . .                        | 61.7  | 85          | 5                  | 82      | 125              | 8         | 2.3       |

Ordonneau subjected 100 litres of 25-year-old Cognac brandy to fractional distillation and obtained the following:

|                                       | Grammes. |
|---------------------------------------|----------|
| Normal propyl alcohol                 | 40.0     |
| Normal butyl alcohol                  | 218.6    |
| Amyl alcohol                          | 83.8     |
| Hexyl alcohol                         | 0.6      |
| Heptyl alcohol                        | 1.5      |
| Acetic ester                          | 35.0     |
| Propionic, butyric and caproic esters | 3.0      |
| Oenanthic ester (about)               | 4.0      |
| Acetal and amines                     | traces   |

It is to one of the esters—oenanthic ester or ethyl pelargonate—that the characteristic flavour of brandy is supposed more particularly to be due. Ordonneau attributes the peculiar fragrant odour to a small quantity of a terpene which in old brandy becomes oxidized. The nature and proportion of the secondary ingredients vary, however, depending primarily upon the character of the wine employed, which in its turn is liable to many varying influences. The type of fruit and the composition of the soil are of first consideration. In the Cognac district, where the soil is mainly calcareous, the fruit is a small white grape with very acid juice, yielding a wine of inferior quality for drinking purposes. The wine produced in the Midi is also unsuitable for drinking and is distilled. This district was one of those ravaged by the *Phylloxera*, a disease which devastated the French vine-growing areas in the years 1875-78. Vineyards which had suffered were replanted with vines which were not appropriate to the soil, the resultant wine being of poor quality. In wines of this character, especially if they have been allowed to become sour, the proportion of acids, esters and other substances which are likely to be distilled with the alcohol and water is high. The method of distillation also has a marked effect upon the ultimate product. In the Cognac district

a small "pot" still is generally used, and this, from its construction, ensures the retention in the distillate of the larger bulk of the volatile ingredients of the wine, to which the well known bouquet of Cognac brandy is due. Care is taken to carry out the distillation very slowly over a wood fire, a quantity of about 200 gallons of wine being operated upon in ten hours.

The spirit obtained from wine of inferior quality and that distilled from the marc contains a high proportion of secondary products. Occasionally this is used for blending with "clean" spirit obtained from grain, beet, etc., the consequent dilution of the secondary products yielding a so-called brandy, the analytical values of which correspond very closely with those of a good brandy. The stills used are of a much more complicated pattern, varying in type from the small pot still with a rectifying head to the elaborate distilling column from which fractions of higher or lower strength can be drawn as desired. A high degree of rectification is possible in apparatus of this character, which is often used for the production of strong spirit for industrial purposes or for the preparation of liqueurs.

**Physiological Effects.**—Although brandy is still used for medicinal purposes—chiefly as a stimulant and as a hypnotic—its application in this connection is decreasing and it has been replaced to some extent by whiskey. The majority of medical witnesses before the Spirit Commission of 1909 appeared to place little value upon the secondary products and ascribed to the ethyl alcohol any beneficial effects of the spirits in the treatment of disease. All alcoholic liquors have an inebriating effect due primarily to the alcohol which is common to them all (*see* ALCOHOL and SPIRITS). Each has effects peculiar to itself, however, and these must therefore be due to the secondary products which according to evidence given by Sir T. Lauder Brunton before the Spirits Commission of 1891 probably individually affect different parts of the cerebellum. Thus, after imbibing an excessive quantity of wine or brandy, a man has a tendency to fall upon his side, whilst it is a generally accepted fact that if the liquor has been mellowed by age its effects are not so potent. From these considerations it would appear that the peculiar effects of brandy drinking may be traced to those substances which, whilst present in the wine from which they pass to the brandy during the process of distillation, are themselves lost or altered in character during the ageing of the spirit. It has been proved that the higher alcohols remain practically unaltered during the maturing process. On the other hand, the furfural, aldehydes and esters undergo considerable change. They have a much more deleterious action upon the human organism and it is to them that the peculiar effects of brandy are due.

**Storage and Maturation.**—It is apparent, therefore, that the question of storage and maturation of brandy is of great importance. The spirit is stored in specially selected oak casks from which it extracts a certain quantity of colouring matter and tannin. It is during this period that the ageing previously referred to takes place. After storage for a varying time depending upon the quality of brandy required and the demands of trade, the spirit is transferred for blending purposes to large vats, where the necessary colouring and sweetening materials are added. In the case of pale brandies the amount added is only about 0.5 to 1%. The modern demand for a darker brandy with its suggestion of age encourages the blender to introduce a larger proportion than this. Brandy which is taken as a liqueur is prepared in this way from the best quality spirit and is stored for several years. The period during which storage is beneficial varies greatly, depending upon the character of the original spirit, the casks used and the place of storage. After this period has elapsed a process of deterioration sets in and develops rapidly. The spirit loses its good flavour and is reduced in strength by evaporation of the alcohol. Thus in one instance, possibly somewhat abnormal, a cask in 1871 contained fifty-eight gallons of brandy having an apparent strength of 112.9% proof. In 1894 the quantity had been reduced by evaporation to forty-nine gallons and the apparent strength to 56.5% proof. When, therefore, the maximum storage period has elapsed the spirit should be transferred to bottles, in which it can remain for many years unaltered. If for trade purposes complete

bottling is not possible, a series of casks of varying ages is used. The spirit required is taken from the oldest cask and replaced by a similar quantity from the next and so on to the newest cask, which is refilled with freshly distilled spirit. The benefits of storage have been recognized officially in the United States of America, where, as previously indicated, the pharmacopoeia prescribes that the spirit "must have been stored in wood containers for a period of not less than four years," and in Great Britain where, under the Immature Spirits (Restriction) Act 1915, brandy cannot be delivered for home consumption unless it has been warehoused for three years.

**Adulteration.**—In the early years of the present century, there was considerable discussion as to the genuine character of much of the spirit sold as brandy and suggestions were made of extensive adulteration or preparation of artificial brandy by the addition of essential oils to grain or potato spirit. The subject was considered by the Royal Commission on Whiskey and Other Potable Spirits and dealt with in its Report of 1909. The information obtained did not support the suggestion as to artificial brandy, but there appeared to be considerable sophistication with neutral spirit. Thus, of 20 suspicious samples examined at the Government Laboratory, 2 gave analytical results which suggested that they were raw spirit coloured and flavoured, 15 appeared to be mixtures of grape spirit and neutral spirit, and 3 afforded no evidence that they contained other than grape spirit. Of 80 examined by a public analyst, 53 were found to be genuine and 27 were mixtures. Although the Commission expressed the opinion that "brandy" referred only to spirits derived from the grape, no standards of identification were recommended. In the previous decade, however, several prosecutions for selling spurious brandy had taken place and the magisterial opinions then expressed resulted in the unofficial adoption by some authorities of certain chemical standards. The wisdom of such a course has been questioned by other experts, it being pointed out that such requirements can readily be satisfied by the addition of artificial esters and higher alcohols to spirit not produced from the grape, a class of fraud even more objectionable than the addition of raw spirit to genuine brandy. The most satisfactory course appears to be the consideration of analytical data combined with expert opinion based upon physical characteristics. (F. G. H. T.)

**BRANDYWINE**, the name of a stream in Pennsylvania and Delaware, U.S.A., which runs into the Delaware river a few miles east of Wilmington (Del.). It is famous as the scene of the battle of Brandywine in the American Revolution, fought on Sept. 11, 1777, about 10 m. north-west of Wilmington, and a few miles inside the Pennsylvania border. Sir William Howe, the British commander-in-chief, while opposed to Washington's army in New Jersey, had formed the plan of capturing Philadelphia from the south side by a movement by sea to the head of Delaware bay. But contrary winds and accidents delayed the British transports so long that Washington, who was at first puzzled, was able to divine his opponents' intentions in time, and rapidly moving to the threatened point occupied a strong entrenched position at the fords over the Brandywine, 25 m. south-west of Philadelphia. Here, on Sept. 11, the British attacked him. Howe's plan, which was carefully worked out and exactly executed, was to deliver an energetic feint attack against the American front, to take a strong column 12 m. up the stream, and crossing beyond Washington's right to attack his entrenchments in rear. Washington was successfully held in play during the movement, and General Sullivan, the commander of the American right wing, misled by the conflicting intelligence which reached him from up-stream, was surprised about noon by definite information as to the approach of the enemy on his right rear. Changing front "right back" in the dense country, he yet managed to oppose a stubborn resistance to the flanking attack, and with other troops that were hurried to the scene his division held its ground for a time near Birmingham meeting-house. But Howe pressed his attack sharply and drove back the Americans for 2 m.; the holding attack of the British right was converted into a real one, and by nightfall Washington was in full retreat northward toward Chester, protected by General Greene and a steady rear-guard, which held off Howe's column

for the necessary time. The British were too exhausted to pursue, and part of Howe's force was inextricably mixed up with the advancing troops of the frontal attack. The American loss in killed, wounded and prisoners was about 1,000; that of the British less than 600. Howe followed up his victory, and on Sept. 27 entered Philadelphia.

**BRANFORD**, a borough of New Haven county (Conn.), U.S.A., at the mouth of the Branford river, 7 m. S.E. of New Haven, on the New York, New Haven and Hartford railroad. The population in 1930 was 2,365. It has a beautiful library, built (1893-96) and endowed by T. B. Blackstone (1829-1900), president of the Chicago and Alton railroad 1864-99, in memory of his father, James Blackstone (1793-1886), who was born and lived all his life on a farm in Braintree, where his ancestors had lived for four generations.

**BRANGWYN, FRANK** (1867- ), R.A., English painter, was born at Bruges, and received his first instruction from his father, the owner of an establishment for church embroideries and kindred objects, who took a leading part in the Gothic revival under Pugin. When the family moved to England, Brangwyn worked for some time in Morris's studio, and then travelled to the East. Indeed, his love of Oriental decorative art exercised a greater influence on him than any early training. His tendency is essentially decorative: a colour-sense of sumptuous richness is wedded to a strong sense of well-balanced harmonious design. Among his decorative panels are "Modern Commerce" in the Royal Exchange, London; those for *L'Art nouveau* in the rue de Provence, Paris; for the hall of the Skinners' company, London; and for the British room at the Venice international exhibition, 1905. The Luxembourg museum has his "Trade on the Beach"; the Venice municipal museum, the "St. Simon Stylites"; the Stuttgart gallery, the "St. John the Baptist"; the Munich Pinakothek, the "Assisi"; the Carnegie institute in Pittsburgh his "Sweetmeat Seller"; the Prague gallery, his "Turkish Boatmen"; and the National gallery of New South Wales, "The Scoffers." Brangwyn turned his attention to many fields of applied art, and made designs for book decoration, stained glass, furniture, tapestry, metal-work and pottery. He also devoted himself to woodcuts and to etching. He was elected R.A. in 1919.

See W. Shaw Sparrow, *Frank Brangwyn and his Work* (1915); H. Furst, *The Decorative Art of Frank Brangwyn* (1924).

**BRANKS or SCOLDING-BRidle**, a contrivance formerly in use throughout England and Scotland for the punishment of scolding women. It seems to have never been a legalized form of punishment; but corporations and lords of manors in England, town councils, kirk-sessions and barony courts in Scotland assumed a right to inflict it. While specially known as the "Gossip's or Scold's Bridle," the branks was also used for women convicted of petty offences, breaches of the peace, street-brawling and abusive language. It was the equivalent of the male punishments of the stocks and pillory. In its earliest form it consisted of a hoop head-piece of iron, opening by hinges at the side so as to enclose the head, with a flat piece of iron projecting inwards so as to fit into the mouth and press the tongue down. Later it was made, by a multiplication of hoops, more like a cage, the front forming a mask of iron with holes for mouth, nose and eyes. Sometimes the mouth-plate was armed with a short spike. With this on her head the offending woman was marched through the streets by the beadle or chained to the market-cross to be giped at by passers. The date of origin is doubtful. It was used at Edinburgh in 1567, at Glasgow in 1574, but not before the 17th century in any English town. A branks in the church of Walton-on-Thames, Surrey, bears date 1633, and as late as 1856 another was in use at Bolton-le-Moors, Lancashire.

See W. Andrews, *Old Time Punishments* (Hull, 1890); A. M. Earle, *Curious Punishments of Bygone Days* (1896).

**BRANT, JOSEPH** (1742-1807), American Indian chief of the Mohawk tribe, known also by his Indian name, THAVEN-DANEAGEA, was born on the banks of the Ohio river in 1742. In early youth he attracted the attention of Sir William Johnson, who sent him to be educated by Dr. Eleazar Wheelock at Lebanon, Conn., in Moor's Indian charity school, in which Dartmouth col-

lege had its origin. He took part, on the side of the English, in the French and Indian war, and in 1763 fought with the Iroquois against Pontiac. Subsequently he settled at Canajoharie, or Upper Mohawk Castle (in what is now Montgomery county, N.Y.), where, being a devout churchman, he devoted himself to missionary work, and translated the Prayer Book and St. Mark's Gospel into the Mohawk tongue (1787). When Guy Johnson (1740-88) succeeded his uncle, Sir William, as superintendent of Indian affairs in 1774, Brant became his secretary. At the outbreak of the War of Independence, he remained pro-British, was commissioned colonel, and organized and led the Mohawks and other Indians allied to the British against the settlement on the New York frontier. He took part in the Cherry Valley Massacre, in the attack on Minisink and the expedition of General St. Leger which resulted in the battle of Oriskany (Aug. 6, 1777). After the war he discouraged the continuance of Indian warfare on the frontier, and aided the commissioners of the United States in securing treaties of peace with the Miamis and other western tribes. Settling in Upper Canada, he again devoted himself to missionary work and in 1786 visited England, where he raised funds with which was erected the first Episcopal church in Upper Canada. His character was a peculiar compound of the traits of an Indian warrior—with few rivals for daring leadership—and of a civilized politician and diplomat of the more conservative type. He died on an estate granted him by the British government on the banks of Lake Ontario on Nov. 24, 1807. A monument was erected to his memory at Brantford, Ontario, Canada (named in his honour) in 1886.

See W. L. Stone, *Life of Joseph Brant* (1838; new ed., Albany, 1865); Edward Eggleston and Elizabeth E. Seelye, "Brant and Red Jacket" in *Famous American Indians* (1879); a *Memoir* (Brantford, 1872); and Frederick Starr, *American Indians* (1898).

**BRANT, SEBASTIAN** (1457-1521), German humanist and satirist, was born at Strasbourg about the year 1457. He studied at Basle, took the degree of doctor of laws in 1489, and for some time held a professorship of jurisprudence there. Returning to Strasbourg he was made syndic of the town, and died on May 10, 1521. He first attracted attention in humanistic circles by his Latin poetry and edited many ecclesiastical and legal works; but he is now known only by his famous satire *Das Narrenschiff* (1494), the popularity and influence of which spread throughout Europe. Under the form of an allegory (a ship laden with fools and steered by fools to the fools' paradise of Narragonia) Brant here lashes with unsparing vigour the weaknesses and vices of his time. Although, like most of the German humanists, essentially conservative in his religious views, Brant's eyes were open to the abuses in the church, and the *Narrenschiff* was a most effective preparation for the Protestant Reformation. Alexander Barclay's *Ship of Fools* (1509) is a free imitation of the German poem, and a Latin version by Jacobus Locher (1497) was hardly less popular than the German original. *Cock Lovell's Bote* (printed by Wynkyn de Worde, c. 1510) is another imitation of the *Narrenschiff*. Cock Lovell is a fraudulent currier who gathers round him a rascally collection of tradesmen. They sail off in a riotous fashion up hill and down dale throughout England. Of Brant's other works the chief is a version of Freidank's *Bescheidenheit* (1508).

Brant's *Narrenschiff* has been edited by F. Zarncke (1854); by K. Goedeke (1872); and by F. Bobertag (Kürschner's *Deutsche National-Literatur*, vol. xvi. 1889). A German translation was published by K. Simrock in 1872, with reproductions of the original fine woodcuts. On the influence of Brant in England, see C. H. Herford, *The Literary Relations of England and Germany in the 16th century* (1886).

**BRANTFORD**, port of entry, Ontario, Canada, on the Grand river, and on the Canadian National, and Toronto, Hamilton & Buffalo railways, and also on the Brantford & Hamilton, and Erie and Northern Electric railways. The river is navigable to within 2½ m. of the town; for the remaining distance a canal has been constructed. Agricultural implements, ploughs, engines, bicycles, stoves, pots, and railway material are made. It contains a provincial institute for the education of the blind and a women's college. The city has the statue of and is named in honour of the Mohawk chief, Joseph Brant (Thayendanegea), who settled here

after leading the Six Nations (Iroquois) on the British side in the American War of Independence; the amalgamated tribes of the Six Nations still make it their headquarters. Pop. (1881) 9,616; (1921) 29,440; (1931) 30,107.

**BRANTING, KARL HJALMAR** (1860-1925), Swedish statesman, was born in Stockholm Nov. 23, 1860, and had a distinguished scientific career as a student at Stockholm and Uppsala. In 1884 he associated himself with the Radical newspaper *Tiden* and shortly afterwards became editor. From 1886 to 1917 he was editor of the *Socialdemokraten*, between 1887-90 and 1892-96, being obliged, for economic reasons, to combine his editorship with work on the Liberal newspaper *Dagens Nyheter*.

When the Social Democratic Labour Party was formed in 1889, Branting was generally considered the greatest intellectual force in the movement. He wished to make the movement a power which, on the one side, would be useful to the working-classes in their economic struggle, and on the other of service to political democracy. It is chiefly due to Branting that the Swedish trade-union movement has always been of a pronounced social-democratic character, and as an organization still keeps in close touch with the Social Democratic Party. The first task of the new party was to mobilise the working-classes in support of adult, equal and direct suffrage, and Branting became a leader in the franchise movement. As early as 1890 he linked up the policy of the Labour Party with that of the progressive middle-class party and made co-operation between them possible. The result was a Liberal-Socialist government in 1917, and in 1918 the constitutional reform which facilitated the spread of social democracy throughout Sweden. He became leader of the party in 1907.

As early as 1897 Branting was a member of the second chamber, where till 1902 he was the only Social Democrat. In face of a powerful Chauvinistic group, Branting, strongly supported by the Labour Party, demanded a peaceful settlement of the question of the separation of Norway from the Swedish crown, and his contributions to the cause of peace when the union was dissolved in 1905, together with his work in the same cause during and after the World War, qualified him for the Nobel Prize which was awarded him in 1921. During the World War he energetically supported the demand for strict neutrality on the part of Sweden, although he displayed a marked sympathy for the Allies.

At the end of the War great hopes were placed on Branting's ability to re-unite the ranks of international social democracy. An attempt had been made in this direction in 1917 at the Swedish-Dutch conference known as the Stockholm Conference, over which Branting presided. He was chairman of the first post-war conference of the Socialist International, held in Bern 1919, and was a member of the permanent international commission for reconstruction within the International.

Branting was appointed delegate to the Peace Conference in Paris in the spring of 1919 and at the negotiations concerning Åland 1919-21. After the entry of Sweden into the League of Nations, Branting was the first representative of his country on the League Assemblies, and in 1922 was a member of the Council.

His defence of the Council of Ambassadors on the occasion of the Corfu incident and his handling of the English-Turkish conflict over Mosul enhanced his reputation.

Branting was Minister of Finance in the Liberal-Socialist cabinet of 1917, and in the spring of 1920 formed Sweden's first Social Democratic ministry. The parliamentary elections in the autumn went against him, but after the election of 1921 he formed a Government which remained in power until April 1923, when it was defeated over the unemployment relief question. After the election of 1924 Branting formed his third ministry, but on Jan. 25, 1925, M. Sandler was appointed prime minister in his place, on account of Branting's ill-health. He died in Stockholm, Feb. 24 1925.

**BRANTÔME, PIERRE DE BOURDEILLE, SEIGNEUR AND ABBÉ DE** (c. 1540-1614), French historian and biographer, was born in Périgord about 1540, or earlier. He was the third son of the baron de Bourdeille. His mother and his maternal grandmother were both attached to the court of Marguerite of

Valois, and at her death in 1549 he went to Paris, and later (1555) to Poitiers, to finish his education. He was given several benefices, the most important of which was the abbey of Brantôme, but he had no inclination for an ecclesiastical career, and became a soldier. He travelled extensively in Italy; in Scotland, where he accompanied Mary Stuart (then the widow of Francis I.); in England, where he saw Queen Elizabeth (1561, 1579); in Morocco (1564); and in Spain and Portugal. He fought on the galleys of the order of Malta, and accompanied his great friend, the French commander Philippe Strozzi (grandson of Filippo Strozzi, the Italian general, and nephew of Piero), in his expedition against Terceira, in which Strozzi was killed (1582). During the wars of religion under Charles IX, he fought in the ranks of the Catholics, but was influenced by the ideas of the reformers. He spent his last years in writing his remarkably frank and naïve *Memoirs*. He died on July 15, 1614.

Of the several editions of the works of Brantôme that by Lalanne for the Société de l'Histoire de France (12 vols., 1864-96) is perhaps the best.

Lalanne's edition has the great merit of being the first to indicate the Spanish, Italian and French sources on which Brantôme drew, but it did not utilize all the existing mss. It was only after Lalanne's death that the earliest were obtained for the Bibliothèque Nationale. At Paris and at Chantilly (Musée Condé) all Brantôme's original mss., as revised by him several times, are now collected (see the *Bibliothèque de l'École des Chartes*, 1904).

**BRANTÔME**, town of south-west France, in the department of Dordogne, 20m. N. by W. of Périgueux by steam-tramway. Pop. (1926) 1,088. The town, built on an island in the river Dronne, it has remains of an abbey founded by Charlemagne about 770 and afterwards destroyed by the Normans. The oldest existing portion is a square tower (11th century). The church, which it overlooks, was originally domed in the Périgord style, but revaulted in the Angevin fashion in the 13th century. The ruined cloister dates from the 15th century. The abbey buildings (18th cent.), now serve as *hôtel-de-ville*, magistrature and schools. The chronicler Pierre de Bourdeille (1535-1614) came into possession of the abbey, from which he took the name of Brantôme.

There are several old houses (12th-14th cents.), a church (15th cent.) and a curious "elbowed" bridge (16th cent.). Several caves, partly natural in origin, are inhabited, and many used as storehouses. Truffles are the chief article of commerce; and there are quarries of freestone in the neighbourhood. The dolmen known as Pierre-Levée, to the east of the town, is the most remarkable in Périgord.

**BRANXHOLM:** see HAWICK.

**BRANXTON** or **BRANKSTON**, a village of Northumberland, England, 2m. S.E. of Coldstream and 10m. N.W. of Wooler. It was on Branxton Hill, immediately south of the village, that the battle of Flodden (*q.v.*) was fought between the English and the Scots on Sept. 9 1513. During the fight the Scots' centre pushed as far as Branxton church, but "the king's stone," which lies N.W. of the church and is popularly supposed to mark the spot where James IV. fell, is some three-quarters of a mile from the scene of the battle; it is probably an earlier monument. Pop. of parish (1921) 184.

**BRAOSE, WILLIAM DE** (d. 1211), lord of Brecknock, Radnor and Limerick, spent the early part of his life fighting the Welsh in Radnorshire. He stood high in King John's favour, received many honours, and was even given the custody of Prince Arthur. But John and he quarrelled, probably over money (1207). In 1208 John began to suspect the fidelity of the whole family, and William had to fly to Ireland. After a number of attempted reconciliations, he was outlawed (1210) and died at Corbeil (1211).

See *Foedera*, i. 107; *Histoire des ducs* (ed. Michel), Wendover; Kate Norgate's *John Lackland*.

**BRASCASSAT, JACQUES RAYMOND** (1804-1867), French painter, was born at Bordeaux; he studied art in Paris, where in 1825 he won a *prix de Rome* with a picture ("Chasse de Méléagre") now in the Bordeaux gallery. His reputation as an artist was made in animal painting. His "Lutte de taureaux" (1837), in the *musée* at Nantes, and his "Vache attaquée par des

loups" (1845), in the Leipzig museum, were perhaps the best of his pictures. He died in Paris on Feb. 28, 1867.

**BRASDOR, PIERRE** (1721-1799), French surgeon, regius professor of anatomy and director of the Academy of Surgery, whose name was long attached to a ligature of his invention. He was an ardent advocate of inoculation. He died in Paris on Sept. 28, 1799.

**BRAS D'OR**, an irregular landlocked and tideless gulf or lake, 50m. long by 20m. broad, almost separating Cape Breton island (Nova Scotia, Canada) into two parts. A ship canal goes across the isthmus (about 1m. wide). The gulf is connected with the Atlantic by the Great and Little Bras d'Or channels, divided by Boulardeire island. The gulf or lake is itself divided into two basins, the inner or Great Bras d'Or lake, from 12 to 60 fathoms deep, the outer or Little Bras d'Or lake, in places nearly 700ft. deep. The picturesque and well wooded shores attract tourists. Sea fishing (cod, mackerel, etc.) is the chief industry.

**BRASIDAS** (d. 422 B.C.), a Spartan officer during the Archidamian War, the first decade of the Peloponnesian War (*q.v.*). He was the son of Tellis and Argileonis, and won his first laurels by the relief of Methone which was besieged by the Athenians (431 B.C.). During the following year he seems to have been eponymous ephor (*Xen. Hell.*, ii. 3, 10), and in 429 he was sent but as one of the three commissioners to advise the admiral Cnemus. As trierarch he was wounded in the assault on the Athenian position at Pylos (*Thuc.* iv. 11, 12).

In the next year, while Brasidas mustered a force at Corinth for a campaign in Thrace, he frustrated an Athenian attack on Megara (*Thuc.* iv. 70-73). Immediately afterwards he marched through Thessaly with a force of helots and mercenaries, and, refusing to join the Macedonian king Perdiccas in a private war, set about breaking up the Athenian empire in the North. During the winter he won over to alliance with Sparta the cities of Acanthus and Stagirus, and, most important of all, the Athenian colony of Amphipolis. An attack on Eion was foiled by the arrival of Thucydides, the historian, at the head of an Athenian squadron. In the spring of 423 a truce was concluded between Athens and Sparta, but Brasidas refused to give up Scione, which, the Athenians declared, revolted two days after the truce began, and occupied Mende shortly afterwards. Therefore fighting still continued in Thrace. An Athenian fleet recovered Mende and blockaded Scione, which fell two years later (421 B.C.). Meanwhile Brasidas joined Perdiccas in a campaign against the Lyncesti, which was at first successful, but ended in a quarrel between Brasidas and Perdiccas, who promptly concluded a treaty with Athens (*C.I.G.* i. 42).

In April 422 the truce with Sparta expired, and Cleon was sent to recover Thrace. By the skilful generalship of Brasidas the Athenian army was routed at Amphipolis and Cleon was slain, but the Spartan general also fell. He was buried at Amphipolis and the sacrifices which had formerly been offered to the Athenian founder were transferred to him (*Thuc.* iv. 78-v. 11). Brasidas and Cleon had been leaders of the war-party, and their deaths enabled Athens and Sparta to conclude the Peace of Nicias (421 B.C.).

Brasidas was the only commander of genius whom the Spartans produced during the Archidamian War. His charm and eloquence, qualities unusual in a Spartan, and his diplomatic treatment of the cities caused the allies of Athens to regard Sparta more favourably and paved the way for widespread revolt after the disaster in Sicily.

See in particular Thucydides, ii.-v.; what Diodorus xii. adds is mainly oratorical elaboration. A fuller account is given in the histories of Greece (e.g., those of Grote, Beloch, Busolt, Meyer and Bury).

**BRAȘOV** (Ger. *Kronstadt*, Hung. *Brassó*), a town of Transylvania, Rumania, centre of the old Saxon district known as the Burzenland, and capital of the Rumanian dept. of Brașov. Pop. (1924) 40,000, of which 15,000 were Magyars, 12,000 Rumanians and 11,000 Germans. Brașov is beautifully situated on the slopes of the Transylvanian Alps, in a narrow valley, shut in by mountains, and presenting only one opening on the north-west towards the Burzen plain. The town is entirely dominated by the Zinne, a mountain rising 1,276ft. above the town (total altitude 3,153ft.).

Braşov consists of the inner town, which is the commercial centre, and the suburbs of Blumenau, Altstadt and Obere Vorstadt, inhabited respectively by Germans, Magyars and Rumanians. To the east of the inner town rises the Schlossberg, crowned by the citadel, erected in 1553. To the north is the ruined tower of the Teutonic Order. Under it the old city wall, with its bastions, is intact. The Protestant church, popularly called the Black Church, owing to its smoke-stained walls, caused by the great fire of 1689, is the finest in Transylvania. It is a Gothic edifice and was built in 1385-1425. In the square in front of it is the statue of Johannes Honterus (1498-1549), "the apostle of Transylvania," who was born in Braşov, and established here the first printing-press in Transylvania. In the principal square of the inner town stands the town hall, built in 1420 and restored in the 18th century, with a tower 190ft. high. Braşov is an important commercial and manufacturing town. Lying near five passes of the Carpathians (Bran, Predeal, Bratocea, Oituz, Buzeu), it developed from the earliest time an active trade with Walachia, Moldavia and the Balkan States. Its chief industries are iron and copper works, wool-spinning, distilleries, turkey-red dyeing, leather goods, paper, cement and petroleum refineries. The manufacture of the wooden bottles used by the peasantry in Hungary and in the Balkan States is carried on. Braşov was founded in 1211 by the Teutonic Order expelled in 1225. It was refounded soon after by Saxon settlers, remaining a main Saxon centre until modern times. Originally situated in the plain, it was withdrawn into the valley after the first Turkish invasions, about A.D. 1400. It played a leading part in the introduction of the Reformation in Transylvania in the 16th century. The town was almost completely destroyed by the big fire of 1689. During the revolution of 1848-49 it was besieged by the Hungarians under General Bem from March to July 1849, and several engagements between the Austrian and the Hungarian troops took place in its neighbourhood. On account of its position it is an excellent tourist centre, being surrounded by beautiful mountains and having several mineral baths in the vicinity.

**BRASS**, a river, town and district of southern Nigeria, British West Africa. The Brass river is one of the deltaic branches of the Niger, lying east of the Rio Nun or main channel of the river. From the point of divergence from the main stream to the sea the Brass has a course of about 100m., its mouth being in 6° 20' E., 4° 35' North. Brass town, formerly a flourishing trading settlement at the mouth of the river, is no longer much used by ship traffic. The capital of the Brass tribes is Nimbé, 30m. up river. The Brass river, called by its Portuguese discoverers the Rio Bento, is said to have received its English name from the brass rods and other brass utensils imported by the early traders in exchange for palm oil and slaves. The Brass natives, of the pure negro type, were noted for their savage character. In 1856 their chiefs concluded a treaty with Great Britain agreeing to give up the slave-trade in exchange for a duty on the palm oil exported. Finding their profitable business as middlemen between the up-river producer and the exporter threatened by the appearance of European traders, they made ineffective complaints to the British authorities. The establishment of the Royal Niger Company led to greater bitterness, for the company's regulations were practically prohibitory for native trade. The Brass men determined on reprisals, and on January 29, 1895, the natives, Christian and pagan, attacked and sacked the company's station at Akassa on the Rio Nun. Forty-three of the prisoners taken back to Nimbé were killed and eaten by the pagan section. The Christian chiefs took no part in this feast and sent back their prisoners (25 in number). In the following March a punitive expedition destroyed Nimbé; 300 natives were killed or wounded. A heavy fine was imposed on the Brass chiefs and the king, Koko, was deposed. The trade regulations of which complaint had been made were removed in 1900 on the establishment of the protectorate of Southern Nigeria.

See the Report by Sir John Kirk on the Disturbances at Brass (Africa, No. 3, 1896); Sir W. N. Geary, *Nigeria under British Rule* (London, 1927).

**BRASS**, an alloy consisting mainly if not exclusively of copper and zinc; in its older use the term was applied rather to alloys of copper and tin, now known as bronze (*q.v.*).

The brass of the Bible was probably bronze, and so also was much of the brass of later times, until the distinction between zinc and tin became clearly recognized. It is quite likely that from very early times brass was made accidentally, owing to the admixture of zinc ores with those of copper, but was not recognized as distinct from bronze. The Latin word *aes* signifies either pure copper or bronze, not brass, but the Romans comprehended a brass compound of copper and zinc under the name of *orichalcum* or *aurichalcum*, into which, according to Pliny, copper was converted by the aid of *cadmia* (a mineral of zinc). One of the earliest examples of Roman brass is a coin of date 20 B.C. containing 17.3% of zinc. There was considerable production of brass in the Low Countries commencing about A.D. 300, and it became an important article of commerce. There are ecclesiastical brasses, or "lattens," still to be seen in many churches, particularly in East Anglia. The word latten is a corruption of the French word *laiton*; and till about 1550 latten was always imported from Flanders and Germany. One of the earliest lattens in England is at Stoke d'Abernon and commemorates Sir John Daubernon (c. 1277). The composition of these lattens is approximately 66% of copper, 1-3% of tin, up to 7% of lead, and the remainder of zinc.

There is good evidence of the manufacture of brass in England in the 16th century, for Queen Elizabeth by patent granted to William Humfrey and Christopher Schuttz the exclusive right of working calamine and making brass. This right subsequently devolved upon a body called "The Governors, Assistants and Societies of the City of London of and for the Mineral and Battery Works," which continued to exercise its functions down to the year 1710. The word "battery" refers to the process of hammering brass into sheets, which was the normal method in England for some 200 years; but by the latter half of the 18th century this method began to be superseded by the rolling-mill, and it is now obsolete. Till 1850 brass was still being made by the calamine process, in which copper shot were heated with calamine and charcoal. The resulting partially-brassed shot were then melted, mixed and cast. This process, however, had been going out of favour since 1781, when James Emerson patented the production of brass from copper and zinc metals, which is the method now in use.

Copper and zinc will alloy in all proportions, but there are several distinct series, known technically as "solid solutions," which are distinguished by the letters of the Greek alphabet, the *alpha* brass having the greatest percentage of copper and being the sole constituent of all wrought brasses containing over 64% of copper. It is to this constituent that brass owes its malleability and general usefulness. The *beta* mixture contains less copper and is of a much harder nature, and as this constituent increases the brass becomes less amenable to cold work, though it can be easily worked hot. The other solid solutions contain less and less copper.

**Brass: Malleable and Non-malleable.**—The brasses may be conveniently divided into two groups by the test of malleability, the dividing line being about the composition of 55% copper and 45% zinc. All the higher copper alloys are workable either hot or cold and in some cases both hot and cold, while the remainder are not malleable at all.

The unworkable brasses are known as the white brasses and are not of great industrial importance. The 50% mixture is much used in a crushed or granulated form for purposes of brazing, and those with lower percentages of copper can be cast and used for sliding parts, since though brittle they offer considerable resistance to frictional abrasion. They also form the basis of certain alloys used for die-casting, a form of casting which has come into much prominence since the war.

The malleable brasses may be further divided into the cold working and the hot working alloys. The dividing line is not precisely drawn, but commercially it is not usual to work alloys of less than 62% copper cold since an excessive amount of annealing would be needed. Hot working above 62% copper is attended with considerable difficulty on account of the very brittle nature

of these alloys when just below red heat, and it does not give the fine structure of the metal and the smooth surface which is obtained with cold work.

The most widely used of the brasses are those of 70% copper and from 62 to 66% copper. The former, which is known as cart-ridge metal and is the most suitable for extreme amounts of work, has mechanical properties, in the cast state, of 15 to 16 tons per sq.in. and 60% elongation; when cold worked, of 30-40 tons and 10% elongation or less; when cold worked and annealed, of 21 tons and up to 70% elongation. The general mechanical properties of brass are very varied; indeed it is this wide range which makes brass such an important alloy. By variation of the composition, or by the amount of cold work put upon the metal, or by the degree of annealing, a tensile strength of from 15 to 45 tons per sq. in., an elongation of from 3% to 70%, and a hardness of from 60 to 150 Brinell can be obtained with all the intermediate degrees. It is readily drawn into fine wire, rolled into strips as thin as .001 in., drawn into tubes and extruded as rods or sections.

**Colours of Brass.**—The alloys of copper and zinc give a remarkable series of colours, of which the most notable are those with about 80% of copper, since they simulate gold, and have names which were once familiar, such as Dutch metal, Mannheim gold, pinchbeck (invented by Christopher Pinchbeck, a London clockmaker, in 1732), and others too numerous to mention. The colours due to composition vary from that of pure copper through yellow to dull white. Brass is susceptible of a fine polish, but tarnishes on exposure to the air; the brilliancy of the surface can however be preserved if the metal is thoroughly cleansed by "dipping" in nitric acid and "lacquered." The brasses also lend themselves to a variety of chemical and heat colour finishes which are quite different from the natural colours of the alloy. Recent research work suggests the possibility of producing a thin, almost invisible oxide film by heat treatment at about 100°C. as a protection against tarnish.

There is a series of alloys which are commonly classed as brasses since brass is their foundation, but they contain other metals also. (See also ALLOYS; COPPER; ZINC.)

**BRASSARD**, originally a piece of defensive armour covering the upper arm (Lat., *brachium*—arm; French, *bras*—arm), now a badge or armet worn on the upper arm.

**BRASS BAND MOVEMENT.** By this name is generally known a movement which has had enormous influence in cultivating and developing musical tastes and aptitudes among the working-classes in England. Originating not far short of 100 years ago in the rival performances of town and village bands, it has since attained, under the stimulating influence of organized competition for substantial prizes, remarkable dimensions. To-day nearly every village has its band and in the larger towns are often to be found several, the total number in existence being put at over 5,000. Most of the large works and collieries have their own organizations, and many of them are known throughout the length and breadth of the land.

Among such bands, Black Dyke mills, St. Hilda colliery, Fodens' motor works, St. Stephens, Carlisle, Wingates, Irwell Springs, Horwich Railwaymen's Institute, Callenders and Luton Red Cross, have all distinguished themselves within recent years by winning the championship and other important contests, while among famous bands of earlier days may be mentioned Meltham mills, Leeds forge, Wyke, Besses o' th' Barn and Kingston mills.

A large number of contests are held in different parts of the country during the summer months but the two meetings which stand out pre-eminently are those held annually at Belle Vue, Manchester and the Crystal Palace, London, the former having been in existence over 75 years. The Crystal Palace meetings in

turn began in 1860, then after a few years existence lapsed until they were re-established in 1900 by Mr. J. Henry Iles, who has been prominently identified with the movement for many years. Under the title of the National Band Festival, in which form they constitute for all concerned the most important and exciting event of the musical year, the chief prize is a trophy of 1,000 guineas for the champion band. As many as 200 bands often take part in this festival the audiences at which have frequently exceeded 20,000.

As regards the music performed, this necessarily consists for the most part of arrangements and transcriptions of compositions of varying orders of merit. At the same time it is worthy of note that the standard alike of the music chosen and of the performances tends steadily to improve; a tendency which has been furthered during recent years by the practice of inviting British composers of standing to write special works for the brass band combination. This consists, in the case of a full band, of 24 players, all the instruments being of the "sax" family, supplemented by three slide trombones; and wonderfully rich and impressive are the results which can be obtained from such a force.

**BRASSEUR DE BOURBOURG, CHARLES ÉTIENNE** (1814-1874), Belgian ethnographer, was born at Bourbourg, near Dunkirk. From 1848 to 1863 he travelled as a missionary, chiefly in Mexico and Central America. He published in 1857-59 a history of Aztec civilization, and from 1861-64 edited a collection of documents in the indigenous languages. In 1864 he was archaeologist to the French military expedition in Mexico, and his *Monuments anciens du Mexique* was published by the French government in 1866. He translated into French the *Popol Vuh*, a sacred book of the Quiché Indians, and wrote a Quiché grammar. In 1871 he brought out his *Bibliothèque Mexico-Guatemalienne*, and in 1869-70 gave the principles of his decipherment, much disputed, of Indian picture-writing in his *Manuscrit Troano, études sur le système graphique et la langue des Mayas*.

**BRASSEY, THOMAS** (1805-1870), English railway contractor, was born at Buerton, near Chester, on Nov. 7, 1805. At the age of 16 he was apprenticed to a surveyor, and on the completion of his term became a partner of his master, eventually assuming the sole management of the business. His first engagement as railway contractor was entered upon in 1835, when he undertook the execution of a portion of the Grand Junction railway, on the invitation of Joseph Locke, who soon afterwards entrusted him with the completion of the London and Southampton railway, a task which involved contracts to the amount of £4,000,000 sterling and the employment of a body of 3,000 men. At the same time he was engaged on portions of several other lines in the north of England, and in Scotland. In conjunction with his partner, W. Mackenzie, Brassey undertook, in 1840, the construction of the railway from Paris to Rouen, of which Locke was engineer. A few years later he was engaged with his partner on five other French lines, and on his own account on the same number of lines in England, Wales and Scotland. In the following year he engaged in the construction of railways in Holland, Prussia, Spain and Italy. One of his largest undertakings was the Grand Trunk railway of Canada, 1,100 miles in length, with its fine bridge over the St. Lawrence. In this work he was associated with Sir M. Peto and E. L. Betts. In the following years divisions of his industrial army of some 75,000 men were found in almost every country in Europe, in India, in Australia and in South America. Besides railway works, he originated a great number of subsidiary establishments, coal and iron works, dockyards, etc. Brassey died at St. Leonards on Dec. 8, 1870. See Sir Arthur Helps *Life and Labours of Mr. Brassey* (1872).

He left three sons, of whom the eldest, THOMAS (1836-1918) was created a baron in 1886 and earl in 1911 on the coronation of George V. He was educated at Rugby and Oxford, entered parliament for Hastings as a liberal in 1868, and devoted himself to naval affairs. He was civil lord of the admiralty (1880-83), and secretary to the admiralty (1883-85). He carried out a number of important enquiries, into wages and conditions of labour in the dockyards, shipbuilding, and design, and into the details of administration in the dockyards. In 1893-95 he was

president of the Institution of Naval Architects. In 1894 he was a lord-in-waiting, and from 1895 to 1900 was governor of Victoria. In 1908 he was appointed lord warden of the Cinque Ports. Among Lord Brassey's publications, his inauguration of the *Naval Annual* (1886 onwards), and his encyclopaedic work on *The British Navy* (1882-83) are the most important. He died in London on Feb. 23, 1918, and was succeeded as second earl by his son Thomas Allnutt Brassey, who died in 1919.

**BRASSICA**, a plant genus of the family Cruciferae (*q.v.*), including the cabbage, mustard (*qq.v.*) and other well-known plants.

**BRASS MANUFACTURES.** The numberless applications of brass, and the different properties which can be obtained by varying the composition and mode of treatment of the alloy, have led in modern times to specialization. The natural consequence has been the segregation of brass manufacture into separate trades or, in the case of large firms, different departments, and although their methods of treatment are similar or in some cases even identical, the distinction is still quite well-defined. In Great Britain there are several separate organizations or associations of manufacturers dealing with the manufacture of brass, and at least as many different trade unions.

It must be realized that the finished product of one manufacturer is the raw material of another. A piece of fine wire gauze may be taken as an example of this segregation of trades; (1) copper and zinc are melted together and cast into an ingot; (2) this ingot is rolled into a strip and slit into sections; (3) these sections are welded together and drawn into wire of medium gauge; (4) the fine wire drawer reduces it to the thickness of a hair; (5) this wire is woven into a gauze. This is typical of brass manufacture as a whole, and it will therefore be convenient to treat the subject under separate heads as follows:

**Sand Casting.**—This form of the alloy is used as the first stage in the production of machined articles. Malleability is not a requisite; a certain shortness or brittleness is advantageous since it makes for ease in machining. Lead from 0.5 to 3% or more is a constituent of the alloy for this purpose and gives hardness and stiffness, a valuable property for some products, *e.g.*, bearings for machinery, gas and water taps, etc. A vast assortment of articles is still produced by casting and machining, though modern practice favours extruded rods and sections wherever possible for repetition work in automatic machines. Since lead and tin are advantageous and other constituents or impurities not injurious, cast brass forms a useful means of using up the brass scrap which is the result of many manufacturing processes. This is an important point in the commercially economic use of metals and saves the expense of refining.

Sand casting of brass is for the most part a "small firm" industry, and it is chiefly carried on by melting in crucibles containing 50 to 100 lb. in pit fires using coke as fuel, the molten metal being poured into sand moulds. These moulds are prepared from patterns in the usual way, as in the case of cast iron. The metal consists of the coarser brands of copper and zinc, copper scrap and brass scrap of various kinds, but it is usually run down or melted into ingots as a preliminary process. No machinery other than the simplest form of hoist for lifting the crucible from the furnace is necessary, and quite a lot of work of this sort is done in Birmingham by one or two men working in a small out-house in their backyard. Simple though this process appears, it is by no means an unskilled operation. Apart from the moulding, a trade in itself, the mixing of the metal, the skimming, and above all the pouring are vital operations in the production of sound castings, and the successful product will depend to a large extent upon the skill and experience of the caster.

**Extrusion.**—Though seized upon and exploited at first by Germany, the extrusion of brass was the invention of an Englishman, Alexander Dick. The alloy used for extrusion has a composition containing from 55 to 62% of copper with usually up to 3 to 4% of lead, and it is cast into an ingot of cylindrical shape, called a billet, as a preliminary process. The common impurities such as tin and iron if not excessive are not deleterious. The process itself is very simple in principle being exactly analo-

gous to pressing grease through a syringe. The hole in the syringe is represented by a metal plate or die having one or more holes of whatever shape may be required, the material is a billet of brass, which has been heated up to a temperature near its melting point and is placed in the cylinder behind the die, while the plunger is an exceedingly powerful hydraulic ram which forces the plastic brass through the holes in the die, thus forming long lengths of round rods or other shapes or sections as they are called. The actual temperature is a matter of importance since the metal can be too hot as well as too cold. The introduction of alloy steels which remain rigid at high temperature has been of great service to the manufacturers of extruded metal and has made possible the production of sections of almost incredible shapes such as the name of the manufacturing firm. Smoothness in the dies is very necessary, as a small defect will cause twisting or weird shapes to make their appearance.

The reduction in price of many turned brass articles is largely due to the use of extruded brass rod in automatic machines. The smooth and continuous running of these machines is dependent on the material being true to size within very small limits and of similar freedom of cutting. Progress in these directions has been so great that manufacturers do not hesitate to contract to supply under stringent conditions. A slight cold drawing to size is quite usual as a finish and also gives a smoother surface. An increasing amount of brass is extruded at about  $\frac{1}{4}$  in. diameter and is then drawn cold into wires as will be explained later under wire drawing. The metal for this purpose will be of a purer quality and contain not less than 60% of copper.

**Cold Work and Annealing.**—Before describing the cold working processes a general description of the effects of cold work and the results of annealing may be helpful since these form the basis of the following processes and a knowledge of them is therefore essential. Of the different ways in which copper and zinc alloy together the most important is the alpha solid solution, which is the copper rich mixture, and it is only when this is the sole constituent, or at least the chief constituent, that cold work is commercially possible. Brass like other metals has a crystalline structure, belonging to the cubic system or highest form of symmetry. When the metal is deformed the crystal structure is broken up and under the microscope the crystals appear to have been turned into long streaks or threads, if the deformation has been carried to a considerable extent. In this state the metal has become hard and is in a condition of strain so that any attempt at further cold work would produce cracking, in fact the metal will sometimes crack spontaneously if exposed to the weather while in this state of strain. It may, however, be restored to its malleable condition by the process of annealing. This consists in heating to a temperature at which it will recrystallize. Some metals recrystallize at ordinary temperature and are said to be self-annealing, but brass does not sensibly alter until it attains a temperature of 300° Centigrade. The first result of annealing at this temperature is to render the metal actually harder, though the strains are eased and the tendency to season-crack is removed. The recrystallization is, however, excessively slow and it would take days or weeks to render the metal again malleable. As the temperature rises the speed of recrystallization increases, until at about 600° a few minutes are required for complete annealing. Under the microscope there can then be seen a closely matted mass of small but beautifully twinned crystals, which is the formation most to be desired by the manufacturer as well as the consumer. Bad casting, overheating or too lengthy a period of heating cause irregularity and large crystals which are always a source of weakness.

**Furnaces.**—For the purpose of annealing a muffle furnace is used and this may be of the open or closed type. In the open type which was formerly the only type in use the chamber or oven really forms part of the flue so that the flames pass over the metal, which is also in direct contact with the flue gases. There is every opportunity for local overheating, which leads to irregular annealing, and only by the exercise of great care can this difficulty be overcome. The only advantage of this type of furnace is the rapidity of heating obtainable with large masses of metal, but

the deposition of dirt, which necessitates much cleaning, neutralizes such advantage so that in England and on the Continent the box type prevails. But in the United States where cheap supplies of distillate oils or gas are available, the open type annealing furnace is commonly used. In this type the fire and flues are separated from the interior by the walls of the furnace through which the heat is transmitted; thus there is no contact between the metal and the products of combustion, and the extra fuel needed is more than compensated for by the saving of cleaning and the preservation of the surface of the metal. Coal, coke, oil and gas are each favoured by different designers as the form of fuel. Electricity has been adopted in some cases for heating and one type of furnace has been introduced in England in which the radiators are placed round the inside of the muffle, thus combining the efficiency and economy of the open muffle with the immunity from dirt and furnace gases given by the box muffle. With the improvement of electric supply this may well become the standard type. A further improvement is the adoption of truck loading, so that a complete loaded truck is run directly into the furnace and replaced by another when finished, the furnace being often built with doors at each end so that the truck runs right through. Another development is the continuous travelling cradle passing through a water seal at each end, the speed being adjusted so that the metal stays the correct time in the furnace. The atmosphere in the furnace is thus kept in a neutral condition, preventing oxidation, red stain and the necessity for cleaning except for final finish. It is usual to control the heat of these furnaces by means of pyrometers of the thermo-electric type.

**Pickling and Cleaning.**—The improvement in the design of muffles has led to a great decrease in the amount of pickling and cleaning required. With the open type of muffle, pickling was necessary after every annealing to remove the dirt, which would otherwise be rolled into the metal and completely spoil the surface, but it is now frequently reserved for the final stages. The process consists in placing the brass in dilute sulphuric acid which dissolves the oxide and loosens the dirt. The metal is then "swilled" or washed in water. All traces of acid must be removed and to ensure this a weak alkali is sometimes used and the metal is then dried by means of sawdust. For metal in a suitable form such as thin strip there are automatic cleaning machines in which the metal passes by means of rollers through the pickling and swilling baths and is dried by steam heated rollers. For the final pickling bichromate of potash or soda is frequently added in small quantity to the sulphuric acid to give a good colour to the metal, and for some purposes the brass is "dipped" or placed for a short time in strong nitric acid, washed and dried. This latter process has an etching effect and destroys the absolute smoothness of the surface. It is then coiled and is ready for the warehouse.

**Cold Rolling.**—The first process in the production of cold rolled metal, as in all brass manufacture, is the casting of the ingot, and much care and attention needs to be directed to this, since the internal structure of the finished strip depends materially on the skill with which the ingot is cast. The underlying principles are similar to those in sand casting but there are important differences in detail. In the first place the metal should ideally consist of copper and zinc only, with no impurities. As this is commercially impossible of attainment the nearest approach to this ideal should be attempted. The increased purity of copper and zinc as a result of the electrolytic methods of production has been of great assistance to the cold roller, and the standard of metal laid down in the B.E.S.A., the A.S.T.M. and other specifications could not have been regularly attained with the old standards of purity. The World War with its demand for millions of brass cartridges had an immense effect in showing the advantage of using pure metals for the manufacture of cold working brass, and it is no longer necessary to increase the percentage of copper in a brass in the endeavour to make the alloy easily workable. The whole series of brasses from 60% upwards of copper is available for cold rolling and most of these alloys are used by different manufacturers for various demands, but there is a distinct tendency to standardize certain mixtures.

The methods of casting employed fall into two classes, namely pit furnaces and crucibles or "pots" dealing with 90 to 150 lb. (in the United States, 100 to 250 lb.) of metal, and electric furnaces dealing with several hundred-weights. The pit furnaces are usually coke or anthracite fired, but gas and oil are also used with success, and in the United States anthracite is frequently employed. The electric furnace is a commercial possibility where large quantities of the same alloy have to be dealt with, especially in the United States, where it is regarded as a normal method. It is also growing in popularity in Birmingham, though the multiplicity of alloys demanded by the British market in comparatively small quantities hinders the change.

For work of this kind the crucible with its small charge has a decided advantage over the electric furnace, which to be economical must be kept at work continuously throughout the 24 hours and does not offer facilities for easy alteration of the composition of the metal. In weighing out the charges of metal or "heats," allowance is made for the loss of zinc during melting. This is kept down by melting the copper and brass scrap first and adding the zinc just before pouring the charge. The metal is poured into iron moulds of varying dimensions depending upon what form, e.g., sheet, strip or wire, is required in the finished article. The pouring of the metal is a skilled operation as the quality of the ingot depends partly on the rate of pouring and also on the filling up of the hollow or "pipe" caused by the contraction on solidification. There has been some move in the direction of following steel practice and using a hot clay top or "dozzle" to the mould. This is filled with molten metal and the feeding is done automatically. Skill is again needed to prevent surface defects, which would cause rough places or splinters when rolled and are known as "spills." In some cases the ingots are planed before rolling in order to eradicate surface defects. The moulds are dressed with various combinations of oil, tallow, resin and charcoal to prevent sticking and to give a reducing atmosphere around the molten metal, thus stopping oxidation. The temperature at which to pour the metal is highly important, but so far no satisfactory means of determining the temperature of the molten metal has been found. The skilled caster tells by the "boiling" of the metal, as felt through the stirring rod, and a competent workman makes few mistakes. The ingots are "cropped," i.e., the "gate" end is cut off by large shears as far as there is any sign of pipe or unsoundness, and are then sent to the rolling mill. In many small works the old method of knocking off the end by taking advantage of the brittleness at black heat is still in use.

The method of brass casting known as the Durville is a departure from usual practice. It is based on the ability to cause molten metal to roll down a trough from one vessel to another without breaking up, especially if it is coated with a skin of adherent material. Such a skin is formed by aluminium oxide if aluminium is added to molten brass before pouring. A special apparatus is used so that the crucible is raised on one end of a "see-saw," the mould being at the other end, and the intermediate member being a trough. The metal rolls down this trough without splashing or breaking up and solidifies with the oxide skin unbroken, the latter keeping the metal from "wetting" the mould. It is claimed that ingots thus produced are free from spill, laminations and other defects, but this also is conditional on the pouring temperature, the heat of the mould, and the steady inversion—in other words, on the skill of the caster. The method is protected.

**Rolling.**—The rolling of metals may be described as an art, for so far it has not been possible to eliminate the skill and judgment of the worker. The amount of reduction at different stages is standardized as far as possible in most mills, but the experience of the roller decides if it is safe to give the last reduction before annealing or whether the metal may be expected to crack. The object in view is to produce metal with a smooth surface and an internal structure of small crystal grain which will allow of the greatest amount of deformation in the later stages. The rolling process divides itself into three main stages, the breaking down, intermediate and finishing. Till comparatively recent times all rolls were made of chilled cast-iron and the majority of heavy or breaking down rolls still are. The introduction of steel rolls, particularly

for finishing, has enabled the mills to produce strip and sheet with a much smoother surface than formerly, and this has proved of great service to the manufacturers of brass articles in that the finished articles are frequently in a condition to be polished without further smoothing. The ingots are passed several times through the breaking down rolls till the reduction amounts to 40 or 50%. The process of rolling hardens the metal so much that at this point it becomes advisable to anneal. After annealing, the strips receive another reduction in the rolls and are again annealed. These alternating processes are continued, the strips going to smaller rolls as they become thinner till they arrive at the highly polished finishing rolls and are brought to the exact thickness required, which will not vary by more than one-thousandth of an inch. Such is the skill of the rollers that limits of two or three thousandths of an inch can be obtained even on the heavy and apparently clumsy rolls. A great deal of machinery has been devised for the easy working of rolling mills. Tandem sets of rolls, reversing rolls, coiling machines, electric drive both of trains and independent rolls have improved the convenience and general appearance of the rolling mills. There is, however, one mill in Birmingham where a James Watt engine still drives the train of rolls with efficiency and economy as it has done for a hundred years.

**Wire Drawing.**—The usual preliminary process of making brass wire is by casting and rolling brass strip to  $\frac{1}{4}$  or  $\frac{3}{8}$  in. thickness. These strips are slit into approximately square sections and the ends are electrically welded so as to form a long length. This wire in embryo is drawn through dies, *i.e.*, plates with taper holes in them of gradually decreasing diameter. The earlier stages are taken one draw at a time, the metal unrolling from one drum, passing through the die and being wound on another drum which is driven and so provides the power for drawing the wire through the die. The wire requires annealing at suitable stages of reduction to restore its malleability. A continuous machine is now used for the finer gauges in which the wire passes through as many as seven dies (in the United States as many as nine) in succession, each one smaller than the last; the wire naturally lengthens as its diameter decreases and the speed increases at every point. Very ingenious methods have been devised to keep a pull on the wire at each successive draw and compensate for the varying speed. Various lubricants are used for wire drawing, the principal bases being oil and soft soap for the larger and very thin oil and soap for the smaller sizes. For the larger sizes steel dies are used, while for the fine gauges diamond dies are found to be most suitable. Wire is supplied either hard drawn, *i.e.*, as it comes from the die, being thus suitable for springs, or more often soft annealed, *i.e.*, having had a final annealing. This last annealing is usually carried out in "pots" (large round pans of cast-iron or nickel chrome) with the cover "luted down" (rendered airtight) with clay to prevent red stain and keep the bright colour of the brass. Red stain is perhaps the chief bugbear of the brass manufacturing industry and has been attributed to various causes by different metallurgists. The adoption of closed muffles, thorough washing and general cleanliness has done much to prevent the trouble arising. This red stain spoils the appearance of rolled metal, but its presence in wire drawing is much more serious since it is very hard and rapidly cuts the dies out of shape. Consequently even the early stages of wire annealing are often carried out in pots.

In the United States, instead of casting brass strips, wire is made by drawing extruded rods or by the hot or cold rolling of cast rods and the drawing of such rods into wire. The process of drawing is the same as that above described, but the wire is drawn from rods rather than from the splitting of strips into square sections.

**Tube Drawing.**—Brass tubes are made in two ways and are known as brazed tubes and solid drawn or seamless tubes. Brazed tubes are made from soft flat rolled strip, the curvature being imparted by drawing through a die. The edges which are then contiguous are soldered with brazing spelter (usually equal parts of copper and zinc) by being passed through a furnace or by the aid of a blowpipe gas jet. Large tubes are bound round with wire at intervals to prevent spreading. The tubes are then drawn down to a certain extent on a mandrel in the usual way. This process is

still used to a large extent particularly where no great circumferential strength is required, since it is much quicker and easier to roll than to draw. The soldered joint is of different composition from the material of the tube, being more brittle, and under internal pressure there is a strong tendency to split longitudinally. Modern practice favours the solid drawn tube as being homogeneous and therefore stronger. For this method the metal is cast in a circular mould with a core up the middle; thus the resulting ingot is in the form of a hollow cylinder and is known as a "shell." Much care is necessary to get a good surface not only on the outside but also on the inside where the core has been. Another way in which tubes may be begun is by "cupping" in a similar manner to cartridge making, *i.e.*, by pushing flat metal through a die with a round nosed punch. The tubes in whichever way they are started are drawn to size gradually on mandrels through dies and require constant annealing. The draw-bench is most simple, consisting of a long iron bed, somewhat resembling the bed of a lathe, with an endless chain, which is driven by power, running along its length. Grips or dogs seize the end of the tube and engage with the chain, thus drawing the tube through the die; the tube is then reversed and the grips draw the mandrel out of the tube. The tubes require pointing or pressing together at the end to enable them to be put through the die and caught by the grips. Nearly all tubes are made of 70% copper alloy, whether brazed or solid drawn. Any alloy with less than 70% copper has a melting point too near that of the brazing spelter, while the extreme malleability of this alloy makes it the most suitable for seamless tubes. For admiralty condensers 1% of tin is added to the alloy which considerably increases its hardness and makes it more difficult to draw. The process of drawing makes greater demands on the malleability of the metal than rolling, and absence of impurities is essential, otherwise constant cracking and breakage will be attendant on the manufacture.

In the United States, brass tubing is mostly made by drawing through a die and over a plug which is held stationary on the end of a steel rod. American brass tubes are generally made from an alloy containing 67% copper if seamless, but of 75% copper, if brazed, alloys containing even 70% copper being usually regarded as too near the melting point of the brazing spelter.

**Ornamental Rolling and Drawing.**—There are some interesting ornamental processes of which mention should be made. Rolls with patterns cut upon them will reproduce this pattern on strip which is passed through them. In this way considerable lengths of "moulded" or embossed metal can be produced suitable for edges or borders. Fluted and oval tubes and other sections can be made by drawing through suitably shaped dies, while the well known twisted pillar is obtained by revolving the die while the drawing process is in operation.

**Spinning.**—This is a process for dealing with thin or moderately thin sheets of metal. The flat piece of metal is held against a wooden chuck in the lathe and worked or spun over or into the chuck by pressing with a highly polished steel tool. The revolving metal gradually takes the form of the chuck. Flower bowls, where the inside is larger than the hole in the top, are spun over a built-up chuck which takes to pieces for withdrawal. Only circular sections can be made, but these may be afterwards altered in shape by other methods. This process puts great strain on the metal so that very careful annealing is required.

**Presswork and Stamping.**—This is the usual way in which brass is shaped to various forms, many of which are familiar as being in everyday use. The articles vary in size from a tiny eyelet made at one blow to the long shell case involving many separate processes. The difference between pressing and stamping is a matter of speed, the former being steady pressure, the latter a blow. The metal may be driven into a die by a punch of the same shape (just as a notepaper press embosses the address) or it may be pressed through the die by a round nosed punch. The difference between the machines lies principally in the method of applying the power to drive the punch, the smallest consisting of a fly press with two heavy balls at the end of a rod working a screw and operated by hand. Other forms include the drop stamp, which is similar to a pile-driving plant, the press worked by a crank or eccentric with a heavy flywheel to accumulate energy for the actual

moment of pressure, and hydraulic presses for very heavy work. In some cases, especially for ornamental fittings, the parts made by these machines are afterwards assembled and soldered together so as to build up a complete whole, often involving artistic design. Of such a nature are many forms of gasoliers and electroliers. Articles made out of wire, such as pins, safety pins, chains, etc., are suitable for production by entirely automatic machines, many of which are highly ingenious and appear almost human in the way they "manipulate" the material. Hot pressings have been much developed lately and now replace many small castings, since the process is well suited to mass production and turns out work to much closer limits. Most of the work so produced goes to the electrical trades.

**Electroplating.**—Brass forms a very good foundation for electroplating with silver, nickel or other metals and was formerly much more used for this purpose, but its position has been largely taken by the nickel silvers, since, when the plating becomes worn, the colour of the underlying metal is not so obvious. Brass can also be itself deposited electrically in an ammoniacal cyanide bath. (See ELECTRO-PLATE MANUFACTURES.)

**Finishing Processes.**—Perhaps there is no metal or alloy which lends itself to such a variety of finishing processes as brass does, or which can be made to simulate so many other metals. The normal colour of brass, which can be varied by alteration of composition, can be further changed by using lacquers of different colours, but it can also be altered by treatment with certain chemicals such as sulphide or a salt of arsenic which gives dark to black colours. Still further alteration can be obtained by heat treatment, which gives different tints according as the temperature is varied. It is usual to cover with a clear lacquer as a final finish to prevent tarnish.

It seems rather unfair that brass, which has so many valuable properties and is almost indispensable for engineering work, should always be associated in the popular mind with shoddiness. It is known as a cheap substitute for oxidized silver or bronze, it used to be a cheap substitute for gold, and it is used as a thin covering for iron to make cheap brass furniture fittings. Not on these uses, nor even on any ornamental uses does the reputation of brass depend, and were all these swept away brass would still take its stand with steel as an alloy of outstanding general adaptability and usefulness.

The following figures from the preliminary reports of the British Census of Production give some idea of the magnitude of the brass trade. The figures include all alloys of copper, other than nickel alloys, though the greater part is brass, and relate to the year 1924, the latest available.

|  | Tons         | Value      |
|--|--------------|------------|
| Sheets and strip                                     | 26,800       | £2,297,000 |
| Wire   | 10,500       | 1,068,000  |
| Rods   | 27,900       | 1,927,000  |
| Tubes  | 11,000       | 1,423,000  |
| Other manufactures (including ingot brass) more than | 46,400       | 4,511,000  |
| Finished brass goods                                 | (not stated) | 7,651,000  |
| Castings, forgings and diecastings                   | (not stated) | 478,000    |

It is impossible to separate the number of persons employed in the manufacture of brass, since the only available figures include copper, aluminium and other metals. A large amount of brass is also produced by railway companies, shipbuilding firms and other large engineering works for their own use or for use in their manufactures and this is not included in the above returns. The export and import figures are similarly grouped with other metallic products.

The methods of manufacture which have been described as in use in England apply equally to France, Germany, the United States and other countries, and may be taken as typical of brass manufacture in general. The brass articles of the East are mostly made from sheet, strip or wire imported from the above countries.

See J. G. Horner, *Brass Founding* (1918); Brit. Engineering Standards Assoc., *British Standard Specification for Brass Bars* (1926); W. G. Lathrop, *The Brass Industry in the United States* (1926). (S. P.)

**BRATHWAIT, RICHARD** (1588–1673), English poet, son of Thomas Brathwait, was born in 1588 at his father's manor of Burneshead, near Kendal, Westmorland. He entered Oriel college, Oxford, in 1604, and remained there for some years, pursuing the study of poetry and Roman history. He removed to Cambridge to study law and afterwards to London to the Inns of Court. On the death of his elder brother, Sir Thomas, in 1618, Richard became the head of the family and an important personage in the county, being deputy-lieutenant and justice of the peace.

Richard Brathwait's most famous work is *Barnabae Itinerarium* or *Barnabee's Journall* (1638), by "Corymbaeus," written in English and Latin rhyme. The title-page says it is written for the "traveller's solace" and is to be chanted to the old tune of "Barnabe." The story of "drunken Barnabee's" four journeys to the north of England contains much amusing topographical information, and its gaiety is unflagging. Barnabee rarely visits a town or village without some notice of an excellent inn or a charming hostess, but he hardly deserves the epithet "drunken." At Banbury he saw the Puritan who has become proverbial,

Hanging of his cat on Monday  
For killing of a Mouse on Sunday.

Brathwait's identity with "Corymbaeus" was first established by Joseph Haslewood. In his later years he removed to Catterick, where he died on May 4 1673.

Brathwait wrote many other works, a full bibliography of which is given in Joseph Haslewood's edition of *Barnabee's Journall* (ed. W. C. Hazlitt, 1876). See also J. Corser, *Collectanea* (Chetham Soc., 1860, etc.).

**BRATIANU, ION** (1864–1927), Rumanian statesman, was born at Florica, Rumania, on Aug. 20, 1864, the son of Ion C. Bratianu. He was educated at the Polytechnic school in Paris and on returning to Rumania became an engineer on the state railways. In 1895 he was elected a deputy as a Liberal. In the following year he was appointed minister of the interior in the Cabinet presided over by D. Sturza, whom he succeeded as prime minister and chief of the Liberal party when the latter retired in 1909. He remained in power until Jan. 1911, when he resigned, but in 1913, after the signature of the Treaty of Bucharest, he again formed a Cabinet. At the opening of the World War Bratianu was in power and it was his Government that guided Rumania's destinies throughout the period. He resigned on Jan. 29, 1918, rather than sign the terms of the peace imposed by the Germans. In Dec. 1918, however, he was again called to power following upon the decision of Gen. Coanda's Government to denounce the separate peace signed with the Central Powers.

Bratianu was chief Rumanian delegate at the Peace Conference in Paris, but he refused to sign the Peace Treaty as a protest against the minority clauses in the treaty and against the division of the Banat of Temesvar between Rumania and Yugoslavia; Bratianu, in accordance with the treaty of alliance concluded between Rumania and the Allies in 1916 claiming that province entirely for Rumania. In consequence he resigned and remained in opposition until Jan. 1922, when he became prime minister again. Bratianu followed closely the policy of consolidation inaugurated by his father, and most of the chief reforms, such as the introduction of universal suffrage, agrarian reform and the settlement of the Jewish question, were enacted during the period when he was in power. From 1922 onwards Bratianu was now practically a dictator; he had with him in the government his brother, Vintila Bratianu, who was minister of finance. The economic policy of the Government, with its suspicious attitude towards foreign capital, was strongly criticized, and Bratianu resigned in March 1926, only to be recalled by the King in June. Bratianu was thus able to "make" the elections, and secured a substantial majority. He supported the king in the plans for the regency when Prince Carol was excluded from the succession, and stoutly opposed proposals for the return of the prince after the king's death. Bratianu was twice married. His second wife was a sister of Prince Stirbey, who was prime minister for a short period in 1927. He died on Nov. 24, 1927. His brother Vintila succeeded him as prime minister, but was displaced at the end of 1928 by Jiuliu Maniu, leader of the Peasant party.

**BRATIANU** or **BRATIANO, ION C.** (1821-1891), Rumanian statesman, was born at Pitesci in Wallachia June 2, 1821. He entered the Wallachian army in 1838, and visited Paris in 1841 for purposes of study. Returning to Wallachia, he took part in the Rumanian rebellion of 1848, and acted as prefect of police in the provisional government formed in that year. The restoration of Russian and Turkish authority shortly afterwards drove him into exile. He took refuge in Paris to work in favour of the proposed union and autonomy of the Danubian principalities. In 1854, however, he was sentenced to a fine of £120 and three months' imprisonment for sedition, and later confined in a lunatic asylum; but in 1856 he returned home with his brother, Dimitri Bratianu, afterwards one of his foremost political opponents. During the reign of Prince Cuza (1859-66) Bratianu was one of the liberal leaders. He assisted in 1866 in the deposition of Cuza and the election of Prince Charles of Hohenzollern, under whom he held several ministerial appointments during the next four years. He was arrested for complicity in the revolution of 1870, but soon released. In 1876, aided by C. A. Rosetti, he formed a Liberal cabinet, which remained in power until 1888. (For an account of his work in connection with the Russo-Turkish War of 1877, the Berlin congress, the establishment of the Rumanian kingdom, the revision of the constitution, and other reforms, see *RUMANIA*.) After 1883 Bratianu acted as sole leader of the Liberals, owing to a quarrel with C. A. Rosetti, his friend and political ally for nearly forty years. His long tenure of office, without parallel in Rumanian history, rendered Bratianu extremely unpopular, and at its close his impeachment appeared inevitable. But any proceedings taken against the minister would have involved charges against the king, who was largely responsible for his policy; and the impeachment was averted by a vote of parliament in February 1890. Bratianu died May 16 1891.

For his writings and speeches see *Ţin Scierile şi cuvîntările lui I. C. Bratianu*, 1821-91 (1903, etc.), edited with a biographical introduction by D. A. Sturza. A brief anonymous biography, *Ion C. Bratianu*, appeared at Bucharest in 1893.

**BRATISLAVA**, capital of Slovakia, Czechoslovakia, is situated at the base of the outlying spurs of the Little Carpathians on the left bank of the Danube where the river is bridged and narrows to pass through the Theben gorge. This strategic situation has been of prime importance in the life and development of the town and, though little is known of the early history of the site, the present town, founded about 1000 A.D., is doubtless not the first settlement. Soon after its establishment strong fortifications were built, and, with the advance of the Turks and the conquest of Buda, it was selected as the Hungarian capital in 1541. This function was retained until 1784, while the Hungarian parliament continued to meet here till 1848. From this time until the end of the World War it was overshadowed by Vienna, but the creation of the Czechoslovakian republic revived its prosperity and it is now the chief Danubian port of the republic as well as its greatest railway junction. Flanked by hills and surrounded by vineyards and parklands the town bears the stamp of its frontier position particularly in its architecture, in the mixture of its population, of whom about 40% are Czechoslovakian, 28% German and 22% Magyar, pop. (1921) 93,189, and in the wealth of educational establishments of all grades.

Supported by many-sided industrial activities such as weaving, milling, iron and leather-working, the manufacture of chemicals, explosives, paper, furniture, tobacco, edible and industrial fats and shipbuilding, and by an active commerce in the grain and wine of its region, it is making a big effort to overtake Vienna as a distributing centre for Balkan trade. In this connection the annual Orient Fair is of importance, and for the effective handling of traffic the port facilities are being greatly enlarged; new quays, railway-sidings and warehouses have been constructed and the scheme of development aims at the creation of a harbour capable of dealing with 3,000,000 tons a year. Bratislava is the seat of the International Danube Commission which, under the Treaty of Versailles, controls navigation on the Danube.

The town itself is an interesting combination of old and new. The fire-scarred shell of the old royal palace situated on the

Schlossberg, a plateau 270ft. above the Danube, dominates everything. Other noteworthy buildings are the Gothic cathedral, the town hall and museum and the Franciscan church, all dating from the 13th century. Bratislava was formerly known as Presburg.

**BRATLANDSDAL**, a gorge of southern Norway in Stavanger amt (county), formed by the Bratland torrent issuing into Lake Suldal. A remarkably engineered road traverses the gorge and the scenery is among the most magnificent in Norway.

**BRATTICE**. In mining, a partition in an airway, constructed to regulate ventilation. A brattice is built of varying materials, according to the nature of the mine; it may be of stone or brick or strong boards. The term is in familiar use both in Britain and the United States, and its origin is found in the German word *brett*, a board. A brattice must be airtight, and when it is constructed of a timber framing it is covered with a "brattice cloth" made of tarred canvas. Sometimes a brattice is made with a sliding door to allow of varying regulation of the air current. See *MINING*.

**BRATTISHING**, in architecture, an ornamental cresting, usually pierced, and occasionally taking the form of a battlement (*q.v.*). The term is generally used of open work forms of great richness, especially foliated forms. It is also used of any richly pierced work in metal.

**BRATTLEBORO**, a village of Windham county (Vermont), U.S.A., on the Connecticut river in the south-eastern part of the State, eight m. from the Massachusetts border. It is served by the Boston and Maine and the Central Vermont railways. The population in 1930 was 8,709. It is an attractive village, situated in a hilly, heavily wooded country, and has some houses dating from the 18th century. There are numerous and varied manufactures. The village was settled about 1753, and was named after William Brattle (1702-1776), a Massachusetts loyalist, one of the original patentees. It was incorporated in 1763.

**BRAUN, KARL FERDINAND** (1850-1918), German physicist, was born at Fulda on June 6 1850 and was educated at Marburg and Berlin. In 1877 he was appointed a professor at Marburg and after appointments at Strasbourg, Karlsruhe and Tübingen, became in 1895 professor of physics and director of the Physical Institute at Strasbourg. He made researches into the electrical phenomena of cathode rays and the problems of wireless telegraphy. In 1909 he received, with Marconi, the Nobel Prize for physics. He died in New York April 20 1918.

**BRAUN, LILY** (1865-1916), German Socialist and writer, was born at Halberstadt. The daughter of Gen. von Kretschmann, she was brought up in an atmosphere of Prussian militarism, but was nevertheless drawn to the Socialist movement. In 1896 she married Heinrich Braun, a Socialist writer and politician. In connection with her interest in Socialism she visited England and met leading members of the Fabian Society. Much of her written work deals with the place of women in politics; e.g., *Die Frauenfrage* (1901); *Frauenarbeit und Hauswirtschaft* (1901); and *Die Politik und die Frauen* (1904). *Im Schatten der Titanen* (1908) is drawn from the life of her grandmother, Jenny von Gustedt, a natural daughter of Jerome Bonaparte. This, with her *Memoiren einer Sozialistin*, published in two volumes, *Lehrjahre* and *Kampfjahre* (1910 and 1911) gave her a European reputation. The *Memoiren*, cast in the form of a novel, was largely autobiographical, and pictured the growth of the German Social Democratic movement at the end of the 19th century. Among her other books are *Die Liebesbriefe einer Marquise* (1912) and *Lebensucher* (1915).

Her son, **OTTO BRAUN** (1897-1918), who fell in the World War, showed a precocious genius. *Aus nachgelassenen Schriften eines Frühvollendeten* (1919) containing poems, essays and pages from his diary, edited by Julie Vogenstein, displays an amazing maturity and has found many readers outside Germany.

**BRAUN, OTTO** (1872- ), German statesman, entered the Prussian Diet in 1912 as a representative of the Social-Democrats and became a member of the *Reichstag* in 1920. From 1918 to 1921 he was Prussian minister of agriculture and an opponent of the landowners. He became Prussian prime minister in March 1920. He is one of the leading members of the Social-Democratic party.

**BRAUNAU:** *see* BROUNOV.

**BRAUNER, BOHUSLAV** (1855– ), Czech chemist, was born May 8 1855, at Prague. He studied chemistry at Prague and also under Bunsen at Heidelberg and Roscoe in Manchester, where, in 1881, he was elected Berkeley fellow of Owens college. In 1883, he was appointed lecturer and in 1890 professor of chemistry at the Czech University of Prague. Brauner devoted himself mainly to the field of modern inorganic chemistry, with special reference to the grouping of the elements in Mendeleyev's periodic system, and did important work on the atomic weights and chemistry of the rare elements. He became a fellow of the Bohemian Scientific Society, a member of the Czech Academy, and a corresponding member of the American Academy of Science.

The results of his extensive chemical research have been issued in numerous publications, the chief of which are as follows: *On Fluorescence* (1877); *On the Atomic Weight of Beryllium* (1878 and 1881); *Contributions to the Chemistry of the Rare Earths* (1882 and 1883); *On the Atomic Weight of Cerium* (1885); *Experimental Studies on the Periodic Law* (1889); *On the Volumetric Determination of Tellurium* (1890); *On the Constitution of Certain Metallic Chlorides* (1889); *Observations on Argon* (1895); *A Method of Preparing Argon in Large Quantities* (1895); *Revision of the Atomic Weight of Cerium* (1903).

**BRAUNSBURG**, a town of Germany, capital of a subdivision of the district of Königsberg, East Prussia, 38m. S.W. of Königsberg, on the Passarge, 4m. from its mouth in the Frisches Haff. Pop. (1925) 13,912. The castle of Braunsberg was built by the Teutonic knights in 1241, and the town was founded ten years later. In 1284, the bishop of Ermeland, who resided there, permitted it to join the Hanseatic League. After numerous vicissitudes it fell into the hands of the Poles in 1520, and in 1626 was captured by the Swedes who kept possession till 1635. It fell to Prussia by the first partition of Poland in 1772. It is a local agricultural centre. Its numerous Roman Catholic institutions include a philosophical and theological high school.

**BRAVO**, the name for a hired assassin such as was formerly common in Italy (It. for "brave"). The word had at first no evil meaning but was applied to the retainers of the great noble houses or to the cavalier-type of swashbucklers familiar in fiction. In later Italian history, especially in that of Venice, the *bravi* were desperate ruffians who for payment were ready to commit any crime.

**BRAVURA** (Ital.), bravery, a term used in music to signify a passage or composition of a brilliant character demanding exceptional powers, with corresponding courage and assurance, on the part of the performer. Thus in the old operas and oratorios a vocal number of this kind would be described as an *aria di bravura*.

**BRAWLEY**, a city of Imperial county, Calif. (U.S.A.), about 22m. from the Mexican border and 10m. from the southern tip of the Salton Sea. It is on Federal Highway 99 and the Southern Pacific Railway. In 1901 a single Indian *wickiup* was the only habitation on the site; in 1910 the population was 881; in 1920, 5,389; and in 1930 it was 10,439 Federal census. The city is 119ft. below sea-level. The temperature ranges from 30° to 115°, with little humidity. The annual rainfall is less than 2in. Brawley is a shipping point for the fruits, vegetables, grain, live stock and other products of the rich Imperial valley. Shipments of perishable products in 1927 amounted to 12,557 carloads, including 6,877 cars of melons and 4,153 cars of lettuce. The city was laid out on the same basic plan as Washington, with wide streets radiating from a central plaza containing the city hall and surrounded by hotels, churches and other public buildings. A fair is held there every winter. Brawley was incorporated in 1908. It has a commission form of government.

**BRAWLING**, in British law, the offence of quarrelling, or creating a disturbance in a church. During the early stages of the Reformation in England religious controversy too often became converted into actual disturbance, and the ritual lawlessness of the parochial clergy very frequently provoked popular violence. To repress these disturbances an act was passed in 1551, and an act of 1553 added the punishment of imprisonment until the party should repent. The Places of Religious Worship Act, 1812, still makes it an offence to disturb congregations for religious worship

permitted by that statute. The acts of 1551 and 1553 were partly repealed in 1828 and wholly repealed as regards laymen by the Ecclesiastical Courts Jurisdiction Act 1860, which is now the statute chiefly relied upon. Under that act, persons guilty of riotous, violent, or indecent behaviour, in churches and chapels of the Church of England or Ireland, or in any chapel of any religious denomination, or in England in any place of religious worship duly certified, or in churchyards or burial-grounds, are liable on conviction before two justices to a penalty of not more than £5, or imprisonment for any term not exceeding two months. This enactment applies to clergy as well as to laity, and a clergyman of the Church of England convicted under it may also be dealt with under the Clergy Discipline Act of 1892 (*Girt v. Fillingham*, 1901, L.R. Prob.176). When Mr. J. Kensit during an ordination service in St. Paul's Cathedral "objected" to one of the candidates for ordination, on grounds which did not constitute an impediment or notable crime within the meaning of the ordination service, he was held to have unlawfully disturbed the bishop of London in the conduct of the service, and to be liable to conviction under the Act of 1860 (*Kensit v. Dean and Chapter of St. Paul's*, 1905, L.R. 2 K.B.249). The public worship of Protestant dissenters, Roman Catholics, and Jews in England had before 1860 been protected by a series of statutes beginning with the Toleration Act of 1689, and ending with the Places of Worship Registration Act 1855 and the Liberty of Religious Worship Act 1855. Obstructing a clergyman or minister officiating in a place of divine worship is a misdemeanour under the Offences Against the Person Act, 1861, and riotous, violent, or indecent behaviour at a burial is a like offence under the Burial Laws Amendment Act 1880.

In the United States similar acts may be punished as breaches of the peace.

**BRAY, SIR REGINALD** (d. 1503), British statesman and architect, was the second son of Sir Richard Bray, one of the privy council of Henry VI. Reginald was born in the parish of St. John Bedwardine, near Worcester, and was receiver-general and steward of the household to Sir Henry Stafford, second husband of Margaret, countess of Richmond, whose son afterwards became King Henry VII. During the reign of Henry VII. he was made high treasurer and chancellor of the duchy of Lancaster. In Oct. 1494 he became high steward of the university of Oxford, and he was a member of the parliament summoned in the 11th year of this reign. His taste and skill in architecture are attested by Henry VII.'s chapel at Westminster and St. George's chapel at Windsor. He directed the building of the former, and the finishing and decoration of the latter, to which, moreover, he was a liberal contributor, building at his own expense a chapel still called by his name and ornamented with his crest.

**BRAY, THOMAS** (1656–1730), English divine, was born at Marton, Shropshire, in 1656, and educated at All Souls college, Oxford. Henry Compton, bishop of London, sent him in 1696 to organize the Anglican Church in Maryland, and he was in that colony in 1699–1700. He interested himself in missions among the American Indians, and was one of the founders of the Society for the Propagation of the Gospel. He also projected a successful scheme for establishing parish libraries in England and America, out of which grew the Society for Promoting Christian Knowledge. From 1706 till his death in Feb. 1730 he was rector of St. Botolph-without (Aldgate, London). Of his writings the best known is his *Catechetical Lectures* (1696).

**BRAY**, a village in Berkshire, England, situated on the right bank of the Thames near Maidenhead. There are numerous riverside residences in the locality. The name is celebrated as that of a well-known ballad, "The Vicar of Bray," which tells how a vicar held his position by easy conversions of faith according to necessity, from the days of Charles II. until the accession of George I. Tradition ascribes the song to George I.'s reign, but the story is usually supposed to have first grown around Simon Aleyn, who remained vicar from 1540 to 1588. Population of parish of Bray (1921) 3,803.

**BRAY**, urban district, Co. Wicklow, Ireland, 12m. S.S.E. of Dublin on the Great Southern railway. Pop. (1926) 8,639. A

harbour was constructed by the urban district council (the harbour authority) to accommodate ships of 400 tons. There is some industry in brewing, milling and fishing, but the town is almost wholly dependent for its prosperity on visitors from Dublin and elsewhere. Its popularity is largely based on the beauty of its surroundings, and it is rapidly increasing in size. About 1170 Bray was bestowed by Richard de Clare or Strongbow, earl of Pembroke and Strigul, on Walter de Reddesford, who took the title of baron of Bray and built a castle.

**BRAZIER**, a metal receptacle for holding burning coals or charcoal, much used in southern Europe and the East for warming rooms (from the Fr. *brasier*, which comes from *braise*, hot charcoal). Braziers are often elegant in form, and highly artistic in ornamentation, with chased or embossed feet and decorated exteriors.

**BRAZIL**, a republic of South America, the largest political division of the continent. It is somewhat larger than the United States, excluding Alaska, is nearly three times the size of Argentina, and 65 times the size of England. Its extreme dimensions from north to south are 2,695 m. and from east to west 2,691 miles. According to the latest calculations its area is 3,285,318 sq.m., comprising about three-sevenths of the entire South American continent.

### GEOGRAPHY AND GEOLOGY

**Boundaries.**—Brazil is bounded by all of the South American republics except Chile and Ecuador, and its territory also touches that of the three Guianas. During the better part of the colonial period the boundaries between Brazil or Portuguese America on the east and Spanish South America on the west were supposed to be the line fixed by the Treaty of Tordesillas (1494), which in turn was based on the line of demarcation drawn by Pope Alexander VI. a year earlier. The Portuguese were persistent trespassers in early colonial times and their land hunger led them to encroach widely on the Spanish claims. By treaties signed by Spain and Portugal in 1750 and 1777 this expansion of Brazil to the westward was recognized and the boundaries then adopted still serve in great part to separate Brazil from its neighbours.

The boundary of Uruguay was settled by treaty in 1851, but was subsequently modified in 1909 when Brazil voluntarily agreed to share with Uruguay the joint control over the waters of Lake Mirim. The line between Brazil and Argentina was defined by the treaty of 1847, but a long and heated controversy arose over the ownership of a region known as *Misiones* adjoining the upper Uruguay river. The dispute was referred to the arbitration of President Cleveland, whose decision, handed down in 1895 favoured in the main Brazil's contentions. The boundary with Paraguay was settled by treaty in 1872. By this instrument certain territorial adjustments demanded by Brazil as a result of her victory in the Paraguayan War were recognized. A thorny dispute with Bolivia over the Acre territory was settled by the Treaty of Retropolis in 1903 through the efforts of the Baron of Rio Branco, the distinguished minister of foreign affairs. This valuable rubber district, comprising over 57,000 sq.m., was ceded to Brazil, which in turn paid Bolivia £2,000,000 sterling and agreed to build a railway around the rapids of the Madeira river, thus giving Bolivia's rich hinterland direct access to the Amazon river. The boundary with Peru was definitely fixed by the treaty of

BRAZILIAN WATER WOMAN

1910, which supplemented the treaties of 1851 and 1858. Ecuador has long claimed to border on Brazil, but her assertion has been disputed by both Peru and Colombia. In 1904 Brazil negotiated a boundary treaty with Ecuador which was to become effective only in case Ecuador could settle its boundary controversy with Peru. But all hope that Ecuador might be contiguous to Brazil vanished when in 1927 Peru and Colombia fixed their boundaries without reference to the claims of Ecuador. A protracted controversy between Colombia and Brazil, which at one time involved fully a third of the great State of Amazonas, was settled in favour of the latter country by the treaty of 1907. The boundary line with Venezuela, defined by treaty of 1859, was settled by protocols signed in 1905. The disputed boundary between Brazil and British Guiana, which involved the possession of territory of some 12,000 sq.m., was submitted to the arbitration of the king of Italy. The decision, rendered in 1904, awarded Brazil nearly two-thirds of the area in question. The Brazilian boundary with Dutch Guiana was determined by the treaty of 1906. The boundary with French Guiana (*see* GUIANA), which had long been a subject of dispute, was settled by arbitration in 1900, the award, almost wholly in favour of Brazil, being rendered by the Government of Switzerland.

### PHYSICAL GEOGRAPHY

**Major Physical Divisions.**—A glance at the relief map of Brazil reveals two very irregular divisions of the surface: the great river basins of the Amazon on the north and the La Plata on the south, which are practically connected by low elevations in Bolivia, and a vast highland or upland region filling in the eastern projection of the continent and extending westward almost to the Bolivian frontier and southward to the plains of Rio Grande do Sul. In addition to these major divisions, which might simply be described as the Brazilian highlands and lowlands, there are a narrow coastal plain and an irregular elevation north of the Amazon and lying only partly in Brazil, known as the Guiana highlands.

**The Lowlands.**—The Amazon river (*q.v.*) and its tributaries drain over a third of the area of Brazil in addition to large parts of the neighbouring republics. The two immense States of Amazonas and Pará lie almost entirely within its basin. Most of this area has an elevation of less than 800 ft. and is subject to heavy rainfall. As a consequence large regions are annually flooded. This abundant moisture, together with the equatorial heat, gives rise to the tropical forests or *selvas*. Nowhere else in the world are to be found woodlands of equal extent. The La Plata basin, on the other hand, is less heavily forested, its surface more varied, and its Brazilian sections have a much higher elevation. The southern half of Matto Grosso as well as large sections of the States of São Paulo, Paraná, Santa Catharina, and Rio Grande do Sul are drained by the La Plata river system.

**The Brazilian Plateau.**—The most important physical division of Brazil is the great Brazilian plateau. It comprises over half the area of the republic. It is larger than the Argentine republic, is seven times as large as France and 12 times as large as the British Isles. In contrast to the sparsely populated Amazon basin it is rightly characterized as the "real Brazil." In extent, population and resources it is in truth an empire in itself. In form it consists of an elevated table-land, from 1,000 to 3,000 ft. above sea-level, traversed by a number of comparatively low mountain chains. The most eastern of these, known as the Serra do Mar, or Coast range, follows the Atlantic coast for nearly 1,000 miles. Though in reality little more than the eastern edge of the great plateau, as seen from the ocean it appears as a practically unbroken range of mountains. From the first it has constituted a barrier to the economic penetration of Brazil and even to-day is crossed by only two standard-gauge railways, and one of these, the São Paulo railway, has to use cables to make the ascent. Many sections of the Serra do Mar bear local designations. Its loftiest peak is generally designated Pedra Açú (7,323 ft.), in the beautiful Organ mountains, which form such an impressive background to the harbour of Rio de Janeiro. The second of the mountain systems, which is separated from the Serra do Mar by a number of river valleys,

PART OF THE HARBOUR OF RIO DE JANEIRO AND THE SURROUNDING MOUNTAINS

To the right is the Bay of Botafogo, a portion of the Harbour of Rio de Janeiro; to the left is the Atlantic Ocean. The high peak in the background is the Corcovado, from the summit of which a view of unsurpassed grandeur is obtained

is the Serra da Mantiqueira. The mean elevation of its crests is about 6,500 ft. and its culminating peak, Mt. Itatiaia (9,823 ft.), is the highest peak in Brazil. The central or Goyana system lies much farther to the west, between the basins of the Tocantins and São Francisco rivers. The importance of the Brazilian plateau can hardly be over-estimated. Thanks to this highland region, partly wooded, partly open prairies or *campos*, immense areas lying geographically within the torrid zone, constitute a satisfactory and, in some cases, ideal habitat for the white race.

**The Guiana Highlands and the Coastal Plain.**—In addition to the great Brazilian plateau there is a mountainous region in the extreme north-east, known as the Guiana highlands. The Brazilian section belongs physically to an isolated mountain system extending eastward from the Rio Negro and the Orinoco to the Atlantic. It is in part forested and in part a hot, stony desert. Up to the present it has been a negligible factor in the progress of Brazil. The narrow coastal plain extends from Cape São Roque on the north to Rio Grande do Sul on the south. It is of varying width, and in some parts of the coast, where the Serra do Mar rises directly from the Atlantic, it disappears altogether. In the extreme south it widens greatly and is merged into an extensive rolling grassy plain characteristic of the neighbouring republic of Uruguay. On this ribbon of littoral are to be found some of the most important cities of the republic, and together with the great plateau it contains nine-tenths of the population of Brazil.

**Rivers and Lakes.**—Outside of the two great river systems of the Amazon and the Rio de La Plata (*q.v.*), the rivers of Brazil are limited to the numerous small streams and three or four large rivers which flow from the great plateau into the Atlantic. Some of these rivers are navigable for a considerable portion of their course and from the earliest times they have afforded means of penetration into the interior. On the other hand their usefulness has been impaired by sand-bars at their mouths, by frequent rapids and falls, and by the lowering of the water-level during the dry season. The Parnahyba ("Bad River") flows northward some 900 m., draining the entire State of Piahy. Though broken by rapids it is navigable for some 400 m. in sections. Of much greater importance is the São Francisco (*q.v.*), the largest river lying entirely within Brazil. Its total length is some 1,800 m., and though broken by rapids and cataracts its course is navigable in its upper sections for nearly 1,000 m. and for 148 m. in its lower reaches. The chief obstacle to navigation is the Paulo Afonso Falls, around which the Government has constructed a railway. The falls have a total drop of 260 ft. and an estimated potential horse-power of over a million. The São Francisco takes its rise in southern Minas Geraes, flows in a north-easterly direction across Bahia, then turns to the south-east, entering the Atlantic at the junction of the States of Alagoas and Sergipe.

Of the rivers flowing into the Atlantic south of the São Francisco only three demand passing notice. The Jequitinhonha rises in north-eastern Minas Geraes and crosses a section of southern Bahia. It has a length of some 500 m., 84 of which are navigable. The Doce also rises in Minas Geraes but reaches the sea through the State of Espírito Santo. Its deep cut through the Serra do Mar has made possible the construction of a railway along its course from the port of Victoria up into the enormously rich iron deposits of Minas Geraes. Its lower reaches are navigable for 138 miles. The Parahyba do Sul (*q.v.*) enters the Atlantic about 30 m. north of Cape São Thomé in the State of Rio de Janeiro. It rises in the State of São Paulo and flows across the State of Rio de Janeiro, through a broad fertile valley producing coffee and sugar. Its length is 658 m. with navigable stretches totaling 147 miles. The remaining streams emptying into the Atlantic are confined for the most part to the narrow coastal plain.

The Brazilian sections of the rivers constituting the Rio de La Plata system are of great importance. Of the Paraguay, which rises near the centre of Matto Grosso, 880 m. are in Brazil. Of these some 600 m. are navigable. Until the completion of the trans-Brazilian railway the Paraguay constituted practically the

sole means of access to the great interior State of Matto Grosso. The Paraná ("Mother of the Sea") is a Brazilian river for over a third of its total length (2,800 miles). With its tributaries it drains the south-western part of Minas Geraes and almost all of São Paulo and Paraná west of the Serra do Mar. The southern parts of Matto Grosso and Goyaz also lie partly in its basin. The Paraná is navigable in long stretches above and below the Sete Quedas ("Seven Falls"), one of the three most famous cataracts in Brazil.

The Uruguay, the third great river of the La Plata system, rises in the Serra do Mar, flows north-westward, forming the boundary between Santa Catharina and Rio Grande do Sul, and later south-westward, forming the boundary between Brazil and Argentina. One-third of its total length of nearly 1,000 m. lies entirely outside of Brazil. Navigation in the Brazilian section is greatly impeded by rapids.

Brazil is ill supplied with lakes. Such as exist are to be found in the coastal plain; for the most part they are lagoons and inland channels formed by uplifted beaches. The most famous are Lagoa dos Patos and Lagoa Mirim, both along the coast of Rio Grande do Sul. The former is 124 m. long and 37 m. wide. At its northern end is the State capital, Porto Alegre, and at its mouth the important seaport of Rio Grande do Sul. Lagoa Mirim, which is slightly smaller, lies partly in Uruguay, although both countries exercise condominium over its waters.

**The Coast.**—The coast-line of Brazil, 3,642 m. in length, is indented with a number of almost land-locked bays, forming spacious and accessible harbours. The largest and most important are the Bahia de Todos os Santos, or simply Bahia, serving the metropolis of northern Brazil, and the magnificent harbour of Rio de Janeiro or Guanabara, beside which stands the capital of the republic. These two harbours are freely accessible to the largest ships afloat. Other important harbours are those of Pernambuco, Espírito Santo, Paranaguá, and São Francisco. Pará, Santos and Rio Grande do Sul are river ports situated near the sea on rivers having the same name. Manáos, the capital of Amazonas, may also be listed among Brazilian ports. Though it lies 850 m. from the sea, the great depth of the Amazon renders it accessible to trans-Atlantic liners. (P. A. M.)

**Geology.**—The older rocks in Brazil consist of intrusive masses and metamorphic rocks—granite, gneiss, quartzite, marble and crystalline schist—which, taken together, have been called the Brazilian complex. They cover in the aggregate a large area, and they are exposed conspicuously in the mountain ranges in the eastern part of the country and in the ranges that border the basin of the Amazon on the north, along the boundary between Brazil and the countries north of it—Venezuela and the Guianas. At some places they are overlaid by Palaeozoic sedimentary beds, which have been greatly disturbed. These Palaeozoic beds contain the veins of quartz that carry the gold now mined in Brazil and that were the source of the gold found in the old placers. They include also great deposits of iron and manganese, and some geologists suppose that they are the place of origin of the diamonds and the other precious stones now mined in Brazil. Silurian, Devonian and Carboniferous beds are exposed in the basin of the Amazon, which in its lower course follows the axis of a syncline composed of them. Rocks of Permian age cover an enormous area in Brazil. They consist mainly of sandstone and shale of detrital origin, but they include also extensive beds of limestone, which are cut here and there by eruptive dikes. The Permian beds in southern Brazil contain seams of coal and the remains of plants, some of which belong to the *Glossopteris* flora, found also in Argentina, as well as in India, Australia and southern Africa. Traces of Permian glaciation, such as erratic boulders, scratched pebbles and glacial till, are found in southern Brazil. The Triassic rocks are soft, reddish sandstone, generally in horizontal beds, which are at some places intruded by dikes of basic eruptive rock. They cover large areas in southern Brazil. Cretaceous marine beds are found in a narrow belt along the coast north of Bahia and they cap hills and cover large areas inland. The Tertiary beds consist of deposits laid down along the shore and in lakes. At several places they contain lignite and bituminous shale. Aeolian

deposits of Tertiary sand and clay cover large areas in Brazil, especially in the basin of the Amazon. The remarkable stone reefs along the north-east coast are ancient beaches that have been hardened by the infiltration of carbonate of lime; they are not coral reefs.

(G. McL. Wo.)

#### CLIMATE

**General Considerations.**—Brazil lies almost entirely within the torrid zone, less than one-twelfth of its area extending south of the tropic of Capricorn. It is often assumed, therefore, that the climate is predominantly tropical. But happily for Brazil the effects of latitude are modified by a number of other factors, such as altitude, prevailing winds, rainfall and distance from the sea. As a consequence there are considerable variations of climate, ranging from tropical in the Amazon valley and along the coastal belt as far south as Santos, to subtropical and temperate throughout large parts of the great Brazilian plateau and the three southern States of the republic.

**Conditions in the North.**—The climatic differences correspond in a general way to the great topographical divisions already noted. The low, forest-clad valley of the Amazon is a region of high temperature with little variation throughout the year. The average temperature is around 80° F and the average rainfall probably falls little short of 80 inches. The period of heavy rains extends from February to June, and the principal dry season from July to October. Easterly winds, which are deflections of the trade-winds, blow up the Amazon valley with great regularity, especially in the dry season. They are warm and moisture-laden. The westerly winds, which blow from the Andes, are cool and dry. They are felt when the sun is north of the equator. The climate of the Amazon valley has the reputation of being unhealthy. The ravages of tropical diseases, especially malaria, have retarded the exploitation and settlement of this region. But in recent years science has robbed the valley of its worst terrors. In a lengthy report submitted to the president in 1913 Dr. Oswaldo Cruz, the distinguished physician who freed Rio de Janeiro from the scourge of yellow fever, indicated that this immense region can be made a reasonably safe habitat for the white race if the same sanitation methods are employed as have been used in Rio de Janeiro, Cuba and the Panama Canal Zone.

**The Coastal Plain.**—Here high temperature and great humidity are the rule until the tropic of Capricorn is passed, although, thanks to the prevailing winds, the temperature is somewhat lower than in regions of corresponding latitude in Africa. The year is usually divided into a winter (*inverno*) and summer (*verão*), corresponding roughly to the wet and dry season, although rain may fall during any month of the year. Going southward there is a slow decrease in the temperature, while the difference between winter and summer becomes more accentuated. Frost and occasionally snow are encountered in the three southern States during July and August, and when the cold south-west storms blow from the Argentine pampas the temperature in the State of Rio Grande do Sul may drop as low as 22° Fahrenheit. The rainfall tends to decrease in volume, going from north to south.

**The Brazilian Plateau.**—The climatic conditions of the great Brazilian plateau differ widely from those of the Amazon valley and the coastal plain. There is much less uniformity in temperature, the difference between night and day being much greater than in localities in the same latitude along the coast. The upland region occupying the eastern projection of the continent and consisting of Piahy and the inland parts of Ceará, Rio Grande do Norte, Parahyba and Pernambuco, frequently suffers from lack of rainfall. In some years the rainy season, which normally lasts from January to May, fails altogether. In such years terrible droughts occur. Crops fail, the livestock perishes and the exodus of a whole population takes place. In the great drought of 1877-80 a large part of the inhabitants of Ceará moved up into Amazonas. The Government has endeavoured to cope with this recurring menace through extensive storage and irrigation works. The climate in this portion of Brazil is not unsuited to Europeans. Though the sun temperature is high, the nights are always cool and refreshing. South and south-west of this semi-arid plateau lie

the table-lands of Minas Geraes, São Paulo and Rio de Janeiro. In this favoured region, the very heart of Brazil, live nearly 40% of the inhabitants, though it constitutes only about 12% of the area of the republic. Rainfall is adequate and the climate ranges from subtropical to temperate. The fertile soil and healthy climate have in recent years attracted a main stream of European immigration into this region, resulting in a marked increase in the white population. The States of Paraná, Santa Catharina and Rio Grande do Sul, lying within the south temperate zone, have a delightful climate and abundant rainfall. Large sections of the great interior States of Matto Grosso and Goyaz are included in the Brazilian plateau. Lying open to the sun and wind, these upland regions have a cool, bracing atmosphere even where the high sun temperature prevails. So healthy is the highland portion of Goyaz considered that the Government has set aside 5,560 sq. m. for the future capital of the republic.

The accompanying table, based largely on the data in Delgado de Carvalho, *Météorologie du Brésil* (1917), indicates the temperature and rainfall at various points in the republic.

| Average Temperature (F)            |         |       |        |                       |
|------------------------------------|---------|-------|--------|-----------------------|
| Locality                           | January | July  | Yearly | Yearly rainfall (in.) |
| <i>Amazon and La Plata basins:</i> |         |       |        |                       |
| Manáos . . . .                     | 77.9    | 78.6  | 78.9   | 59.5                  |
| Pará . . . . .                     | 75.9    | 78.2  | 75.3   | 94.0                  |
| Cuyabá . . . .                     | 79.8    | 76.02 | 77.5   | 50.9                  |
| <i>Littoral:</i>                   |         |       |        |                       |
| Pernambuco . .                     | 81.3    | 75.2  | 79.8   | 76.1                  |
| Bahia . . . . .                    | 76.6    | 71.6  | 76.8   | 75.3                  |

**Fauna and Flora.**—The most noteworthy and characteristic examples of Brazilian fauna are to be found in the Amazon valley and are dealt with in AMAZON, FLORA AND FAUNA OF (*q.v.*). While the Atlantic littoral and the Brazilian highlands are moderately rich in animal life all the important species found here are likewise represented in the Amazon basin. This last statement is somewhat less true of the Brazilian flora. Along the coastal plain and in the subtropical and temperate regions of the republic are many kinds of trees and plants rarely if ever found in the Amazon valley. Especially is this true of the economic plants and fruits of Brazil, both indigenous and exotic, such as coffee, sugar-cane, tobacco, maize, rice, maté and a great variety of palms. A brief account of these plants will be found later in this present article in the section dealing with agricultural resources and industries; while other details are available in the articles devoted to the individual States.

#### PEOPLE

**The Indian.**—Brazil was discovered and settled by the Portuguese, who gave the country its language and basic racial type. The first explorers found a widely scattered Indian population, relatively low in the scale of civilization. The absence of women among the early colonists led to marriage with the Indian women and a *mestizo* or *mameluco* element appeared, traces of which are still to be found in northern Brazil, especially in Ceará. Statistics regarding the Indian population are little more than estimates. According to General Mariano da Silva Randon, who is in charge of the service for the protection of Indians (organized in 1910), some 1,500,000 still dwell in Brazil. Many of them are receiving instruction and guidance in Government reservations, of which, in 1923, there were 35 in nine different States. There is reason to believe that the Indian population is slowly increasing.

**The Negro.**—The introduction of African slaves began in the middle of the 16th century, and though legally forbidden after

1831 continued for another two decades. The colour-line is not sharply drawn in Brazil, and intermarriage with the white races has been frequent. According to the census of 1872 the total population was 9,930,478, of which 1,510,806 were slaves; the race enumeration gave 38.1% whites, 19.7% Africans, 38.3% mixed bloods and 3.9% Indians. The last census in which classifications were made according to races was taken in 1890. The total population

had risen to 14,333,915, made up of 44% whites, 14.6% negroes, 32.4% mixed bloods and 9% Indians. A comparison of the census figures indicates that the indigenous increase of the whites has been greater than that of the African and mixed races. This fact is due in part at least to the higher infant mortality among the negro elements. The increase of the proportions of whites has also been greatly accelerated during the last four decades by the large influx of European immigrants. The Brazilian population is apparently undergoing a transformation by which the mulatto element is increasing in relation to the pure negroes, while falling behind in relation to the pure whites. This process, called by the Brazilians the "arianization" of the race, will result, in the opinion of some authorities, in the disappearance of the pure negro element by the end of another century.

**The Immigrant.**—The racial character of the people is not uniform throughout the republic, the whites predominating in the southern States, the Indians in Amazonas, and the mixed races in the central and northern coast States. The rapid increase of white population in the south has been due to the stream of European immigration, which has been pouring into this section. The introduction of immigrants from Europe dates from 1818, when a Swiss colony was located at Nova Friburgo, near Rio de Janeiro, and it was continued under the direction and with the aid of the Imperial Government down to the creation of the republic. Since then both the Federal and the States Governments have encouraged immigration. The immigrants either have been located in so-called "colonies," where they remain under Govern-

THE SANTA THERESA AQUEDUCT AT RIO DE JANEIRO, BRAZIL, BUILT DURING THE COLONIAL PERIOD

southern Europe furnished more than 80% of all the immigrants. Since 1908 the ratio in these nationalities has completely altered; the Portuguese have taken the lead, followed by the Spaniards and the Italians. In recent years Japanese immigrants have found their way to Brazil, where they are employed in the rice plantations in São Paulo. In 1926 the number of arrivals was 7,552. The total German immigration from 1820 to 1920 was only 131,441. The importance of this element, of which so much has been written, especially during the World War, for political ends, has been greatly overestimated. In 1925 the German contingent—immigrants and their descendants—probably did not exceed half a million. They are found for the most part in the southern States and form a most desirable body of settlers.

Immigration, which in 1913 amounted to 192,684, almost entirely ceased during the World War. The last few years have witnessed a resumption, though not on a pre-war scale, the figures for 1926 being 67,171. It is fair to assume that the number of immigrants will slowly increase. During the next 50 years Brazil could advantageously absorb 100,000 immigrants annually without adversely affecting the homogeneity of its population, provided these additions were more evenly distributed than has been the case in the past.

**Population Statistics.**—The census of 1920 gives a population of 30,635,606, including 1,565,951 foreigners. The density of population for the country as a whole was 9.3 per square mile in contrast to 649 per square mile for England and Wales and 35.5 per square mile for the United States. The population is very unevenly distributed, being largely concentrated on a relatively narrow strip of coastal plain and the eastern portion of the central plateau. The three States of Amazonas, Matto Grosso and Pará, comprising over half the area of the country, contain only one-twentieth of the population. On the other hand, were the entire republic as thickly populated as the State of Rio de Janeiro the total population of Brazil would exceed 400,000,000. The accompanying table gives the names, areas and population of the 20 States, the territory of Acre, and the Federal district, together with the names and population of their capitals. For purposes of comparison the census figures for 1900 rather than for 1910 are given, as the census for the latter year was notoriously incomplete.

| States                        | Area sq. m. | Population  |             | State capitals               | Population census 1920 |
|-------------------------------|-------------|-------------|-------------|------------------------------|------------------------|
|                               |             | Census 1900 | Census 1920 |                              |                        |

ment tutelage until they become economically independent, or have been placed on the large plantations, chiefly coffee, under formal contract. The total number of immigrants registered from 1820 to 1920 was 3,648,382. Of this total more than a third, namely, 1,388,881, were Italians; next came the Portuguese with 1,055,154, while the third largest group were Spaniards, who furnished a total of 510,514. Thus the three Latin countries of

According to the *Retrospecto Commercial* of the *Jornal do Commercio* for 1926 the population of Brazil on Dec. 31, 1926 was 36,870,972.

#### POLITICAL ORGANIZATION

**Organization of the Government.**—The overthrow of the monarchy on Nov. 15, 1889 resulted in the creation of a Federal republic under the name of the United States of Brazil (Estados

Unidos do Brasil). The present Constitution, promulgated Feb. 24, 1891, and amended Sept. 3, 1926, follows in the main the constitution of the United States of America. The republic consists of 20 States, the Federal district, and the territory of Acre. The relations between the national and State Governments are carefully defined. The former has the exclusive right to direct the foreign affairs of the republic, to maintain an army and navy, to levy import duties, to regulate foreign commerce, to issue money, and to maintain the postal and telegraph service. To the States are left all those faculties not expressly denied them by the Federal Constitution. Chief among these are the right of self-government, the right to levy export taxes, the exclusive control of the public lands, mines and industries. They are charged with the support of primary education, the maintenance of order and the support of a system of State courts. According to the Constitution as originally adopted, the National Government is forbidden to interfere in the States except to repel invasion, to maintain a republican form of government, to enforce the execution of Federal laws, and to re-establish order at the request of the States themselves. The amendments of 1926 considerably expanded this right of interference. The Federal Government may intervene for instance "to reorganize the finances of any State whose inability to lead an autonomous life shall have been demonstrated by the discontinuance for more than two years of payment of its funded debt." (Art. 6, par. 4.)

**The Executive Power.**—The Constitution clearly recognizes the principle of the separation of powers: "The organs of the national sovereignty are the legislative, the executive, and the judicial power, harmonious with and independent of each other." The executive power is vested in a president, elected for a term of four years by a direct vote of the electors. He must be a native of Brazil, over 35 years of age. He is ineligible for the succeeding term. A vice-president is elected at the same time and under the same conditions. He succeeds to the presidency in case the office becomes vacant during the last two years of the presidential term. If the vacancy occurs during the first two years a new election must be held. The president receives a salary of 120,000 milrêis and 265,000 milrêis for expenses of his residence, the equivalent of about £10,000 in all. The ministry contains seven portfolios, viz., foreign affairs; finance; agriculture, industry and commerce; traffic and public works; justice and internal affairs; war; marine. The ministers are responsible to the president, who appoints or removes them with absolute discretion. The president sanctions or vetoes laws passed by congress, is in supreme command of the army and navy and possesses wide appointive power. (One of the amendments adopted in 1926 authorizes him to expel from Brazil any foreign subject dangerous to the public order.) The powers of Federal intervention and declaration of a state of siege, though subject to the control of congress, are in reality largely exercised by the president. Both constitutionally and politically the Brazilian executive is stronger than the president of the United States.

**The Legislative Power.**—The legislative power is vested in a national congress of two chambers elected by direct suffrage. The senate consists of 63 members (three from each State and the Federal district) elected for nine years. The chamber of deputies contains 212 members elected for three years on the basis of one deputy for each 70,000 of population according to the apportionment of 1892. Despite the constitutional provision for a re-apportionment on the basis of the decennial census no change in the number of deputies has been made. The chamber has the right of initiative in laws dealing with the budget or numerical strength of the army and navy. The members of both houses receive a *per diem* subsidy and an allowance for expenses.

**The Judicial Power.**—The judicial system consists of a supreme Federal tribunal of 15 judges in the national capital and a district court in each of the 21 units of the federation. One member of the supreme tribunal holds the position of solicitor-general of the republic. The judges and solicitor-general are appointed for life by the president with the approval of the senate. The supreme tribunal has original and appellate jurisdiction and like the Supreme Court of the United States has power to pass on the

constitutionality of Federal and State laws. The district Federal courts have original jurisdiction in Federal causes. Brazil has Federal codes covering the domain of civil, criminal and commercial law.

**State and Local Government.**—In the main the Governments of the 20 States are similar to that of the Union. The separation of powers is observed, at least in theory. In practice the governmental functions of the various States reveal wide divergences due to differences in population and resources. In populous and progressive States like São Paulo and Minas Geraes a genuinely democratic régime prevails and public opinion finds full expression. In some of the thinly populated States, where conditions are backward, political power is concentrated in the hands of a few large landholders, sometimes even in a single family. The Brazilians themselves describe them as "feudal States." Municipalities, of which in 1920 there were 1,300, in theory enjoy a large amount of self-government, with an elective council and a prefect. In practice, save in the case of the larger cities, the municipalities are subject to the political control of the State administration. The prefect of the Federal district is appointed by the president of the republic.

#### EDUCATIONAL SYSTEMS

Though marked progress has been made in recent years, the educational system in Brazil is still unsatisfactory. According to the census of 1920 illiteracy ranged from 38% in the Federal district to 88% in the State of Piauh. For the entire republic the figures are 75.5%, or 64.9% of the population over 15 years of age. There is no ministry of public instruction in Brazil but only a national department of education within the ministry of justice and internal affairs. With the assistance of the national council of education this department exercises supervision over primary education in the Federal district and the Acre territory and secondary and higher education throughout the republic. A law passed in 1924 authorizes the Federal Government to grant aid to the States for the maintenance of rural schools in the immigrant settlements.

**Primary Education.**—Primary education is free but not compulsory save in the States of Ceará, Maranhão, Alagoas, Matto Grosso, Minas Geraes, São Paulo and Santa Catharina. Except as noted above, it is under the control of the States and municipalities. In 1925 approximately £1,500,000 was expended by the States for elementary education and £400,000 by the Federal Government. The returns for 1920 show 1,249,449 pupils enrolled in 12,748 elementary schools, the great majority of which have a course of only four years.

**Secondary Education.**—Secondary education is provided by the Federal Government, by the States and by private agencies. The courses in the Government schools, known as *collegios*, *gymnasios*, *lyceus*, were fixed in 1925 at six years. The Collegio Dom Pedro II., located in the capital, is the only Federal secondary school in Brazil. It is regarded as a model for all other schools of its kind. In 1924 there were 56 secondary schools under Government control or supervision. In addition there were a large number under private auspices, many of them maintained by the Catholic Church and by Protestant churches in Great Britain and the United States. Some of these schools have collegiate departments. Among the best of these institutions founded or maintained under Protestant auspices are Mackenzie college in São Paulo and Collegio Bennett in Rio de Janeiro. Normal schools, in some cases combined with secondary schools, are to be found in the State capitals and in Rio de Janeiro. In recent years their standards have risen noticeably. The normal school at São Paulo is one of the best in South America.

**Higher Education.**—Higher education, wholly of a professional character, was given in a number of independent faculties until 1920, when the University of Rio de Janeiro was created by the amalgamation of the faculties of law, medicine and engineering. In 1924 there were in Brazil ten law faculties, six schools of medicine, six schools of engineering, besides a number of schools of pharmacy and dentistry. The Federal Government also supports four military schools, a naval academy and several schools of agriculture. Finally there are a number of professional,

technical, commercial and trade schools under Federal or State control. The State School of Mines at Ouro Preto in Minas Geraes should be singled out for special mention.

**Museums, Art Galleries and Libraries.**—Several museums of note are to be found in Rio de Janeiro. The former palace of Dom Pedro II. at the Quinta da Boa Vista has been transformed into a museum of geology and natural history. An excellent historical museum, especially rich in mementos of the imperial epoch, dates from the centenary of Brazilian independence (1922). The National school of art contains collections of the old masters as well as many works of Brazilian artists, notably those of Pedro Americo de Figueiredo. The National library, whose foundation goes back to 1807, contains over half a million volumes and a wealth of manuscript material. In the suburbs of São Paulo, on the site of the proclamation of Brazilian independence in 1822, is the Paulista museum, containing one of the best natural history collections in South America.

**Learned Societies.**—Of the many learned societies in Brazil but two call for mention. The Brazilian Academy of Letters, founded in 1889, is modelled upon the French Academy. Its 40 members include many of the names famous in Brazilian literature. The Brazilian Historical and Geographical Institute (Instituto Historico e Geographico Brasileiro) is the oldest South American historical society now in existence. It dates from 1838 and its quarterly review is a vast repository of material on Brazilian history and geography.

#### RELIGION, CHARITY AND PUBLIC ASSISTANCE

Under the empire the Roman Catholic Church had been recognized and supported by the State, but with the advent of the republic (1889) Church and State were entirely separated. Civil marriage, the civil registration of births and deaths, and the secularization of cemeteries followed. Yet the overwhelming majority of the Brazilians are at least nominally Catholic, as is also true of the bulk of the immigrants. Ecclesiastically Brazil is divided into 20 dioceses under the archbishop of Rio de Janeiro, who was raised to the dignity of a cardinal in 1905. Complete religious toleration has long prevailed in Brazil and Protestantism has made some progress, especially in the domain of education. In 1923 there were 120 evangelical centres and 700 organized churches, most of the latter being small. The Lutheran Church, whose pastors are largely recruited from Germany, claimed 342 congregations, 195,700 members, and 200 parochial schools.

Religion and charity have always been closely associated in Brazil. Hospitals and asylums have been established by the Catholic Church throughout the country. A *Misericordia* hospital and a *recolhimento*, or asylum for orphan girls, are to be found in all the larger cities and towns. In 1922 the income of the hospitals in Rio alone amounted to 5,634 contos (some £136,000). In recent years the more progressive cities have expended large sums for public health and public assistance in general. These activities, which are closely co-ordinated with those of the Church, are in the capital under the general supervision of the *Departamento Municipal de Assistencia Publica*. Athletics, especially football and baseball, arouse great interest in Brazil. They have been encouraged by the public authorities and by the well-organized Young Men's Christian Associations.

#### FINANCE

**Public Revenues and Expenditures.**—The national revenue is derived in considerable part from duties on imports, the duties on exports having been surrendered to the States when the republic was organized. Since 1899 a varying percentage of the import duties—amounting to 60% by the budget law of 1923—has been paid in gold in order to supply the Government with specie needed for its foreign remittances. In all official reports the revenues and expenditures have therefore been calculated in gold and currency together, to the complete mystification not only of the foreigner but even of the average Brazilian. The gold milrêis, which is never seen in circulation, has a value of approximately 27d. The value of the paper milrêis varies according to the rate of exchange. One thousand milrêis constitute a conto de réis. The following table gives in contos the revenue and expenditure

for the years 1922–27, the figures for the last three years being estimates derived from the president's messages.

| Year | Average rate of exchange pence | Revenue    |             | Expenditure |             |
|------|--------------------------------|------------|-------------|-------------|-------------|
|      |                                | Gold conto | Paper conto | Gold conto  | Paper conto |
| 1922 | 7.00                           | 75,379     | 653,475     | 83,766      | 1,074,179   |
| 1923 | 5.32                           | 99,037     | 743,275     | 92,068      | 997,032     |
| 1924 | 5.96                           | 102,890    | 921,898     | 87,339      | 915,132     |
| 1925 | 6.15                           | 101,296    | 890,341     | 87,289      | 1,012,749   |
| 1926 | 6.55                           | 101,986    | 947,566     | 83,994      | 976,493     |
| 1927 | 5.95                           | 122,073    | 1,071,725   | 107,133     | 1,055,453   |

The figures for the budgetary estimates for 1927 converted into pounds sterling (at 6d. exchange) reveal a revenue of £47,300,000, with an expenditure of £44,900,000, leaving a surplus of £2,400,000. But from this surplus must be deducted £2,200,000 bonus to public officials, leaving a net surplus of £200,000. If this estimate proves correct the year 1927 should mark a turning point in the financial history of Brazil. For the first time in many years the budget will have been balanced. Deficits were not uncommon during the empire but under the republic they have been the rule. For instance, the aggregate deficits for the years 1891–1904 were the equivalent of £43,240,000 and more recent years have revealed little improvement.

**Revenues of the Federal Government.**—The most important sources of revenue, as revealed in the budget proposals for 1926, are as follows (conversion at 6d. exchange):

|   |             |
|---|-------------|
| Customs dues, port taxes, dock dues . . . . .   | £12,689,635 |
| Consumption and excise taxes . . . . .  | 7,385,500   |
| "Circulation" taxes (i.e., taxes on invoices, transport and mercantile sales) . . . . . | 5,564,750   |
| Industrial revenues . . . . .   | 5,619,775   |
| Income tax . . . . .  | 1,762,500   |
| Extraordinary revenue (i.e., minting, taxes on industries and professions) . . . . .    | 1,544,050   |
| Miscellaneous . . . . .   | 596,145     |
| Total . . . . .   | £35,162,355 |

From this table it will be seen that a large proportion of the national revenue comes from indirect taxation, customs dues alone accounting for more than one-third of the total income. The income tax, which first appears in the budgetary estimates for 1924, has proved difficult to collect, and represents barely 5% of the entire revenue of the Federal Government.

**Expenditures of the Federal Government.**—These may be made clear by the following table, likewise taken from the budgetary estimates for 1926:

| Ministry                                     | Alloiment   |
|--|-------------|
| Justice and internal affairs . . . . .       | £2,428,900  |
| Foreign affairs . . . . .                    | 643,445     |
| Marine . . . . .                             | 2,489,395   |
| War . . . . .                                | 4,470,974   |
| Agriculture, industry and commerce . . . . . | 1,145,967   |
| Traffic and public works . . . . .           | 9,252,230   |
| Finance . . . . .                            | 13,429,793  |
| Total . . . . .                              | £33,861,704 |

It should be noted that the expenditures of the Ministry of Finance, which include the service of the foreign and internal debt of the republic, amount to about 40% of the total. The Government-owned railways make the heaviest draft on the budget of the ministry of traffic and public works. The funds expended by the ministry of justice and internal affairs are for the most part devoted to education and public health, those expended by the ministry of agriculture to colonization and the support of agricultural schools.

**Foreign and Domestic Debts and Investments.**—Brazil's foreign debt is partly a legacy of the empire. When the republic was established in 1889 it amounted approximately to £30,000,000. Since then the debt has been greatly increased and on two different occasions, the Government was forced to recur to funding loans with a temporary suspension of the sinking fund. Prior to 1908 all the loans were floated in London, from 1908 to 1916 considerable loans were raised in France and since 1921 heavy borrowing

has been made in the United States. The Federal Government has never repudiated its foreign obligations. On Dec. 31, 1925, Brazil's national debt stood as follows:

|  |              |
|--|--------------|
| Foreign debt:  | £102,529,944 |
| Francs   | 336,548,500  |
| Dollars  | 63,717,167   |
| Approximate total in pounds sterling   | 118,674,299  |
| Internal funded debt: 2,137,424 contos or £62,341,542                        |              |
| Floating debt: 35,526 contos gold and 3,162,195 contos paper, or £95,666,500 |              |
| Total of foreign, internal, and floating debt:                               | £276,682,341 |

In Sept. 1926 the foreign obligations of the States amounted to £32,717,722, Frs. 256,487,500, and \$77,511,000, making an approximate total in pounds sterling of 50,776,975. At the same date the outstanding foreign indebtedness of the Brazilian municipalities amounted to £10,777,508, Frs. 373,665,000, and \$14,930,000, the equivalent in pounds sterling of 16,912,414. There are no reliable statistics available regarding the internal indebtedness of the States and municipalities.

Naturally, complete accuracy in regard to foreign investments is impossible, but the following figures, brought up to June 30, 1924, are believed to be approximately correct:

|  |                    |
|--|--------------------|
| <i>British investments</i>               |                    |
| Industrial enterprises                   | £121,005,544       |
| Loans to Federal Government              | 102,633,294        |
| Loans to State and Municipal Governments | 60,636,430         |
| Total                                    | 284,275,268        |
| <i>French Investments</i>                |                    |
| Industrial enterprises                   | Frs. 1,500,000,000 |
| Government loans                         | 717,561,800        |
| Total                                    | 6,217,561,800      |
| <i>United States investments</i>         |                    |
| Industrial investments                   | \$100,000,000      |
| Loans to Federal Government              | 123,717,167        |
| Loans to State and Municipal Governments | 118,700,000        |
| Total                                    | 342,417,167        |

A conservative estimate of the capital invested by Germany, Italy, Portugal, Netherlands and Belgium would be £60,000,000.

The Brazilians are alive to the disadvantage of a fluctuating currency and the Government is taking steps towards putting the national finances on a gold basis. In 1923 the Federal Government transferred to the Bank of Brazil for a period of 50 years the sole right to issue currency; late in 1926 and early in 1927 legislation was enacted providing for the stabilization of the milréis. Henceforth the milréis is to be regarded as the gold equivalent to 200 milligrams of gold  $\frac{1}{10}$  fine (equal to 6d.) and a new unit of currency called the *cruzeiro*, having a value of 10 milréis, is to be adopted. (One pound sterling equals 4.067 *cruzeiro*.) All the paper money in circulation (2,569,304 contos—approximately £62,000,000) is to be redeemable in gold. This operation is to take place by means of a "stabilization fund" (*caixa de estabilização*) to be provided by the Government.

#### DEFENCE

**Army.**—The army consists of the active or regular army and first line reserve, and the second line army with the reserve. In 1925 the nominal strength of the active army was 4,969 officers, 622 sergeants and instructors, and 42,393 privates. Its organization includes 70 battalions of infantry and 13 machine-gun companies, 19 regiments of cavalry of four squadrons each, 18 regiments of field artillery, and seven battalions of engineers. Military service, under the law of 1923, is in theory obligatory on all Brazilians from 21 to 44 years of age. Service in the active army consists of one to two years' training in the ranks, eight years in the reserve, and 14 years in the second line army (seven in the National Guard and seven in the National Guard reserve). It is estimated that mobilization would put 100,000 men in the field. The requisite effectives are recruited by voluntary enlistment without bonus, and if this does not supply the necessary number, by compulsory service based on the drawing of lots. Military instruction is given in the Realengo Military academy at Rio. The military organization is provided with an elaborate code and a system of 12 military courts which culminates in a supreme military tribunal. (P. A. M.)

**Navy.**—In the year 1905 the Brazilian Navy lost its principal unit by the destruction of the armoured turret ship "Aquidaban" by a magazine explosion in the Bay of Jacarepagua near Rio de Janeiro; but a naval programme was introduced in that same year, making provision for an appreciable modern fleet, and the principal units of the Brazilian navy are still the ships completed in the year 1909 under that programme. These include the two "dreadnought type" battleships "Minas Geraes" and "São Paulo" of 19,200 tons, armed with twelve 12in. and twenty-two 4.7in. guns, mounted similarly to those in the original British "Dreadnought"; two cruisers, the "Bahia" and the "Rio Grande do Sul" of 3,150 tons, armed with ten 4.7in. guns. An old coast defence ship and an obsolete cruiser complete the heavy ships of the Brazilian navy. There are eleven destroyers, all dating from 1908 to 1910, except one, formerly H.M.S. "Porpoise," 1914; and four submarines, three launched at Spezzia in 1914, and one more modern, the "Humayta," also built in Italy and completed in 1927. The remainder of the fleet is made up of small auxiliary vessels and river gunboats. The main naval base and naval school are situated at Rio de Janeiro. There are smaller arsenals at Para, Pernambuco, São Salvador and Ladario. (E. A.)

**Air Services.**—During recent years growing attention has been devoted to the Air Force as an element of national defence. The military flying school, located in the suburbs of the capital, gives the necessary training to air pilots, observers, mechanics and expert artificers. A company of engineers is attached to the school. Among the special troops are listed 12 Air Force flights. The navy also maintains a well-equipped school. It is located on Governador island in the harbour of Rio de Janeiro.

#### ECONOMICS AND TRADE

**Agriculture.**—"Taking Brazil as a whole, no country in the world, owned by a European race, possesses so large a proportion of land available for the support of human life and productive industry." Thus does Lord Bryce (*South America, Observations and Impressions*, p. 404) bear witness to the enormous wealth, for the greater part still unexploited, locked up in Brazil's boundless extent of fertile land. Though Brazil is essentially an agricultural country, only 20% of its 2,000,000,000 ac. is occupied as farm lands, and of these lands barely 20%—an area equal to twice the size of England—is actually cultivated, the remainder being pasture and forest land. Between one-half and two-thirds of the cultivated area is to be found in the three States of São Paulo, Minas Geraes and Rio Grande do Sul.

| Crop                                 | Region                                   | Yield                         | Value           |
|--------------------------------------|--|-------------------------------|-----------------|
| Coffee<br>5,500,000 ac.              | São Paulo<br>Minas Geraes                | 12,000,000<br>bags of 132 lb. | £<br>50,000,000 |

## INDUSTRIES OF BRAZIL

1. Field of sugar-cane on one of the farms under the management of the Brazilian agricultural school at Piracicaba, in São Paulo
2. Santos, Brazil, the largest coffee-shipping port in the world. View of the docks showing carloads of coffee ready for exportation
3. Cotton-picking on one of the large plantations in São Paulo. Cotton-raising is one of the principal industries in this section
4. Packing hides for exportation in the state of Rio Grande do Sul; many tons are shipped yearly to the United States and Germany
5. General view of a textile mill in Petropolis, a suburb of Rio, where there are a number of factories and threading, cotton and silk mills
6. A tobacco plantation in the vicinity of São Feliz and Cachoeira, Bahia, a centre of tobacco-growing

### HARBOUR AND URBAN VIEWS OF RIO DE JANEIRO AND SANTOS

1. The Avenida Beira-Mar, boulevard along the harbour of Rio de Janeiro, looking towards Botafogo, a resident suburb of Rio de Janeiro
2. Sidewalk cafés on the Avenida Rio Branco. Café owners are permitted to place their tables close to the edge of the pavement
3. View of the Avenida Rio Branco. The street is one of the fashionable promenades of Rio de Janeiro. The white building on the left contains the offices of the *Jornal do Commercio*
4. General view of Santos, a Brazilian seaport on the Atlantic coast. It is probably the greatest coffee exporting centre in the world

cording to the *Retrospecto Commercial* the total estimated value of the principal Brazilian crops for 1924-25 was 7,843,932 contos (approximately £188,000,000).

Of these various crops the most important is coffee. From two-thirds to three-fourths of the coffee production of the world is furnished by Brazil. Seventy per cent of this coffee is grown in the State of São Paulo, and one-half of the total crop is marketed in the United States.

**Pastoral Industries.**—During the past quarter century pastoral industries have made enormous strides in Brazil. By the census of 1920 there were in Brazil 34,271,324 bees, 5,253,699 horses, 1,865,259 mules and asses, 7,933,437 sheep, 5,086,655 goats, 16,168,549 hogs. Both the National Government and the more progressive States have done much to improve the quality of the cattle stock. The establishment during the World War of modern slaughtering and meat-packing plants gave the industry an immense stimulus. In 1928 there were 10 of these plants, largely owned by American and British capital. From 1917 to 1921 the exports of frozen and chilled meats averaged over 60,000 metric tons a year. There is still a large demand for *xarque* or jerked beef and some 70 plants, supplying some 50,000 metric tons, are devoted to the salting and drying of this meat. With the immense areas in central and southern Brazil adapted to cattle raising, Brazil seems destined eventually to outstrip Argentina, the United States and Australia as the greatest purveyor of the world's meat supplies.

**Fisheries.**—Brazil is provided with an astounding variety of fishes, nearly an eighth of the approximately 20,000 known species being found along her coast and in her rivers. Though a considerable fishing population is to be found along the Atlantic seaboard and in the Amazon basin the fishing industry has never assumed a major importance, and cured fish, especially cod, continues to be a staple import. That there are considerable possibilities is obvious.

**Forest Industries.**—Here the chief items are rubber, *maté* or Paraguayan tea, Brazil nuts, vegetable wax, palm fibre, cabinet and other woods and the products of medicinal plants. Rubber is the chief product of the Amazon basin. In 1905 it represented 32% of the value of Brazil's exports, but fell in 1925 to less than 5%, due to the successful competition of the plantation-grown rubber of the East. The dried leaves of *maté* or Paraguayan tea, which grows extensively in the temperate regions of Brazil, finds a ready market in the Plate republics. The export of cabinet woods is small, due to the cost of transporting timber to the coast. In recent years the pine forests in temperate Brazil, especially in Paraná, have been extensively exploited. But the forest industry is still in its infancy and we have the curious spectacle of the country with the greatest timber resources in the western hemisphere, if not in the world, exporting only 133,293 metric tons of lumber in 1925.

**Mineral Wealth.**—The yield from Brazil's mineral resources lags in value far behind the products of her plantations, pastures and forests. The annual gold output, which reached large proportions during the 18th century, now amounts to some £600,000. It comes from two very deep British-owned mines in Minas Geraes. Diamonds are found in Minas Geraes and Bahia. The most valuable are probably the *carbonados* or black diamonds, chiefly used in drills for cutting purposes. The value of the average annual yield is probably less than £300,000. Manganese, a metal indispensable in the making of steel, is found in large quantities in Minas Geraes. By all odds the most important of the potential mineral resources of Brazil is iron. The deposits in Minas Geraes are of almost fabulous extent. According to conservative estimates they contain over 12,000,000,000 tons of high grade ore. Unfortunately Brazil contains none of the coking coal necessary for smelting, while electric smelting is too expensive to be practicable. Bituminous coal of poor quality (20 to 55% ash content) is found in Rio Grande do Sul and Santa Catharina. Some 400,000 metric tons were mined in 1925, as against 1,619,687 metric tons imported from England and the United States. Thus far no petroleum in paying quantities has been found in Brazil.

**Manufactures.**—Since the establishment of the republic it has been the avowed policy of the Government to encourage manufacturing industries by means of a high protective tariff. According to the census of 1920 there were 19,735 factories employing some 350,000 operatives. The capital employed exceeded £100,000,000. By 1925 the value of the yearly output had risen to approximately £200,000,000, an increase of nearly 100% over the figures for 1915. Textiles easily take the lead. At the beginning of 1926 Brazil had 257 cotton mills equipped with 2,345,809 spindles and 70,561 looms, and employing 114,065 operatives. The largest and most progressive of the factories are located in and about the cities of Rio de Janeiro and São Paulo. In a score of manufacturing lines, including shoes, hats, tobacco, matches, Brazil is virtually independent of imports. Other important manufactures are silk, clothing, dairy products, furniture, canned fruit and vegetables and paper.

**Foreign Commerce.**—Although the figures for Brazil's imports and exports are at first sight imposing, the total trade for a nation as large and populous as Brazil is relatively small. The per caput foreign trade is only about £5 sterling, as against £24 sterling for Argentina. This is due in part to the fact that Brazil, with its immense variety of resources, produces a great part of the things the country needs. The growth and extent of Brazil's foreign commerce during the last quarter century are revealed by the following table:—

| Year           | Imports in pounds sterling | Exports in pounds sterling |
|----------------|----------------------------|----------------------------|
| 1901 . . . . . | 21,377,000                 | 43,621,000                 |
| 1905 . . . . . | 32,739,000                 | 44,653,000                 |
| 1910 . . . . . | 47,871,000                 | 63,901,000                 |
| 1913 . . . . . | 67,166,000                 | 64,849,000                 |
| 1920 . . . . . | 125,000,000                | 107,521,000                |
| 1924 . . . . . | 68,337,000                 | 95,103,000                 |
| 1925 . . . . . | 84,443,000                 | 102,875,000                |

The most important articles imported in 1925, together with their value in thousands of pounds sterling, are as follows:—machinery and tools, 11,880; wheat, 7,365; iron and steel, 6,317; cotton goods, 5,158; motor cars, 4,329; wheat flour, 3,570; coal, coke and patent fuel, 3,553; gasoline, 2,338.

Similar data regarding exports for 1925 are as follows:—coffee, 74,020; rubber, 5,058; cotton, 3,307; *maté*, 2,857; cacao, 2,626; tobacco, 2,342; chilled and frozen meat, 1,716.

Statistics for the chief countries of origin of imports for 1925 are as follows:—United States, 20,772; Great Britain, 18,770; Germany, 11,774; Argentina, 9,837; France, 4,904; Italy, 3,073; Belgium, 2,836. Similar data regarding Brazil's principal markets for the same year:—United States, 46,468; France, 12,947; Germany, 6,876; Italy, 6,563; Netherlands, 6,279; Argentina, 5,572; Great Britain, 5,182.

## COMMUNICATIONS

**Railways.**—Railway development in Brazil has been impeded by a number of obstacles of which the most important is the plateau escarpment following the coast. At the beginning of 1926 the total railway mileage amounted to 19,026 m. of which one half is concentrated in the three central States of Rio de Janeiro, Minas Geraes and São Paulo. Several hundred miles are under construction and several thousand surveyed or projected. The Federal Government owns 11,152 m., 4,576 m. belong to the States and 3,298 m. are privately owned. In recent years it has been the policy of the Government to lease to private companies all of its lines except the Estrada de Ferro Central, which is operated by the Federal Government for political and sentimental reasons. The "Central," as this railway is generally called, is 1,563 m. in length. The main line between Rio de Janeiro and São Paulo has a gauge of 5 ft. 3 in.; the branches, of which the most important extends up into Minas to Pirapora, the head of navigation on the São Francisco river, have for the most part a metre gauge. Though it carries more than 60,000,000 passengers annually its balance sheet shows a deficit. Of the private lines the most profitable and best equipped is the São Paulo

railway, an English company, connecting São Paulo with Santos. There is rail connection between Rio and the Uruguayan and Argentine systems, while the recently completed North-Western practically reaches the Bolivian frontier. On the other hand the independent systems radiating from Bahia and Pernambuco are entirely cut off from central Brazil. In the State of São Paulo some 90 m. of the Paulista railway (a Brazilian company) have been electrified.

**Steamship Routes and Resources.**—Brazil has excellent steamship service with Europe, while several well-equipped lines furnish connections with the United States. By the terms of the constitution of 1891 coastwise navigation is restricted to Brazilian companies with the exception of the Amazon, which has been open to ships of all nations since 1867. By regulations adopted in 1892 and 1913 foreign ships stopping at two or more Brazilian ports are permitted to transport passengers and certain kinds of freight. The Brazilian merchant marine in 1922 consisted of 556 steamers of 522,663 gross tons and 107 sailing vessels of 41,535 gross tons. Of the five important companies, all enjoying Government favours or subventions, the most important is the Lloyd Brasileiro, a corporation in which the national Government owns a majority of the stock and nominates the directors. With its 82 ships with a gross tonnage of 266,247, it not only maintains service between the chief maritime and fluvial ports but also runs a line to the United States. Since 1923 its annual balance sheet has shown a surplus.

**Aviation.**—With the immense distances and inadequate means of communication between many populous centres Brazil offers a promising field for the establishment of airways. Both the ministry of public works and the Brazilian aero club have endeavoured to arouse interest in civil aviation but up to 1927 no regular service had been established.

**Roads.**—The advent of the automobile presages a radical transformation in Brazilian rural life. Thanks to the motor-car whole communities, hitherto isolated or stagnant, are being brought into contact with the outside world. The Government is fully alive to the need of good roads. In 1926 legislation was passed levying increased duties on petrols and auto products, the proceeds to be used exclusively for road building and maintenance. At the National Highway Congress held in 1926 a comprehensive plan for future road development was adopted. Even now there are some 50,000 m. of highway of which 6,500 may be described as first-class. In 1926 there were 121,000 automobiles in Brazil, according to the *Retrospecto Commercial*.

**Telegraphs, Cables and Wireless.**—In 1926 50,562 m. of telegraph line were in operation including 11,217 m. of submarine cable. Three cable lines, operated by English, French and Italian companies respectively, run between Brazil and Europe. An American company has a line connecting Brazil with the United States, while a British company operates a submarine cable laid on the bed of the Amazon between Pará and Manáos. In 1926 there were 12 wireless stations, all the property of the Federal Government. Ten are located at points on or near the littoral, one in Amazonas, and one in the Acre territory. Some 30 radio broadcasting stations were in operation in 1926.

### HISTORY

**Discovery and Settlement.**—The discovery and early settlement of Brazil appear in the larger perspective of history as episodes in the great movement of Portuguese colonial expansion to the east. Vasco da Gama's discovery of an all-water route to the

Indies and Spice islands by the Cape of Good Hope in 1498 led the Portuguese crown to despatch to India an imposing armada under Pedro Alvares Cabral, whose sailing directions had been drawn up by the great Vasco himself. To avoid the calms off the Gulf of Guinea Cabral bore so far to the west that on April 22, 1500, the mainland of South America was sighted and the region was promptly claimed by Portugal, as it lay well within the zone assigned Portugal by the Treaty of Tordesillas (1494). (The coast of Brazil had been touched early in the year 1500 by the Spanish navigator Vicente Yañez Pinzon but the Spanish crown made no effort to follow up the discovery.) Portugal's new possession was at first called the "Island of the True Cross," a name soon abandoned in favour of Brazil after the valuable dye-wood in which the country abounded. The tidings of Cabral's discovery aroused great enthusiasm and further explorations were undertaken. According to the generally accepted account the first of these expeditions, which set sail on May 10, 1501, had as its pilot Amerigo Vespucci (*see* VESPUCCI, AMERIGO), who had already been once and possibly twice to the New World. As the little fleet sailed along the coast of Brazil—whose immense extent was for the first time realized—Vespucci, calendar in hand, baptized the different points on the coast with the names of the saints on whose days they were discovered. A majority of these names (*e.g.*, Cape São Agostinho, São Francisco river) have remained to the present day. It is probable that the spacious bay of Guanabara was entered on Jan. 1, 1502, and named Rio de Janeiro.

For over a quarter of a century following Vespucci's voyage interest in Brazil all but ceased. No precious metals were discovered and the energies of the Portuguese were increasingly absorbed by the establishment of a great empire in the East. Portugal's enemies and rivals, especially the French, were quick to take advantage of this neglect. Swift corsairs from Honfleur and Dieppe loaded their ships with the valuable Brazil-wood and even attacked Portuguese vessels returning from the Indies. Brazil became a sort of no man's land over which the Portuguese crown wielded only a shadowy control. This apathy came to an end, however, with the accession of John III. (1521–1557) and the centre of gravity in colonial affairs began gradually to shift from Asia to America.

The first systematic effort to establish an organized government in Brazil was made in 1532. Brazil was divided into 15 hereditary captaincies or fiefs, extending 50 leagues along the coast and an indefinite distance inland. These grants were distributed to favoured persons, chiefly courtiers, who took the name of *donatarios*. Their rights and privileges were extensive. They were authorized to found cities, issue land grants, levy internal taxes, and appoint municipal officers. To the crown was reserved the right to impose export taxes and the monopoly of Brazil-wood and spices. The captaincy system failed to realize the hopes of the crown. Only 10 of the fiefs were occupied by their owners and of these only two were really successful. The most flourishing of the settlements was that of São Vicente, south of the present city of Santos. This had been granted to Martim Affonso de Souza, who in 1530 had explored the coast as far south as the La Plata estuary and had penetrated for some distance into the interior. By the middle of the century the captaincy had a population of some 5,000, including the growing port of Santos and the town of São Paulo, over the edge of the Serra do Mar, on the fertile plateau of Piratininga. In northern Brazil Duerto Coelho had converted the captaincy of Pernambuco into a great sugar-producing region. But the remaining captaincies were for the most part tragic failures. The *donatarios* were generally incompetent and tyrannical and the struggling settlements were powerless against attacks of hostile Indians or the depredations of French corsairs.

**Royal Control.**—At length fully alive to these perils King John determined to substitute for the inefficient rule of the *donatarios* a unified, centralized administration. Brazil was brought directly under royal control through the appointment of a governor-general. The first to hold this office was Thomé de Souza, a Portuguese noble who had gained wide experience in India. In 1549 he took up his new duties at Bahia, which remained the capital of Brazil for the next 200 years. The governor-general was

granted wide powers in civil and criminal affairs. The donatarios were obliged to surrender their political and judicial rights, though they were allowed to keep possession of their fiefs until they were acquired by the crown. Local officials, responsible to the governor-general, were placed over the captaincies, and strategic points along the coast were fortified. In the cities municipal organizations, similar to those in Portugal, were established. Brazil now began to attract settlers in increasing numbers. By 1600 Bahia and Pernambuco each had a population of 2,000 whites, with over twice as many negro slaves and converted Indians.

A factor of great importance in the progress of the colony was the labour of the Jesuits. At the instance of John III. several fathers accompanied the first governor-general, Thomé de Souza, to Bahia. Among them was Manuel Nobrega, the first of a long line of missionaries who devoted their lives to the protection and conversion of the Indians and to the raising of the moral level of the colonists. At the site of the present city of São Paulo, Nobrega established a school for the training of missionaries. Here he was joined by José de Anchieta, whose heroic labours among the Indians won for him the title of the "Apostle of Brazil." As rapidly as the Indians were converted they were settled in villages or "aldeas," similar to the missions in Spanish America. The activities of the Jesuits soon aroused the antagonism of the colonists, particularly the "Paulistas," the name given to the hardy and tough-fibred settlers of São Paulo. The colonists demanded an abundant labour supply and as white labourers were lacking they proceeded to enslave the Indians and to force them to work on their plantations. Both the Jesuits and colonists appealed to the crown; the former won a partial victory by the decree of 1574, which granted to the Jesuits full control over the Indians in the "aldeas" while permitting the colonists to enslave Indians captured in legitimate warfare. In the north the storm centre of a somewhat similar conflict was Father Antonio Vieira, who in the 17th century established a chain of missions in the Amazon valley. Naturally the restrictions on Indian labour stimulated the introduction of negro slaves, a movement which steadily gathered momentum after the middle of the 16th century.

**Dutch and French Aggression.**—Brazil had hardly been brought under royal authority before a determined effort was made by the French to establish a permanent colony. The prime mover in this enterprise was a French adventurer and soldier of fortune named Nicholas de Villegagnon, who contrived to enlist the support of Admiral Coligny and even Calvin by the assurance that the future colony would be an asylum for Huguenots and other Protestants. King Henry II. lent his sanction and in 1555 the French took possession of the beautiful harbour of Rio de Janeiro, which the Portuguese had strangely neglected to occupy. But Villegagnon failed to rise to his opportunities. He showed little skill as a colonist. His promise of religious toleration was broken. Attempts at forceful conversion to Catholicism alienated the support of the Protestants. Rumours of these dissensions reached Europe and checked what might have become a great migration from France and Geneva. Meanwhile the Portuguese had come to realize the extent of the French menace. A large force under Men de Sá, the governor-general, blockaded the entrance to the harbour and forced the French garrison to surrender. To ward off future attacks Men de Sá in 1567 founded the city of Rio de Janeiro. Although subsequent attempts were made by the French to gain a foothold in Brazil—notably by Duclerc and Admiral Duguay Trouin in 1710 and 1711—the hope of establishing "Antarctic France" as a pendant to the French colonies in North America was never realized.

From 1580 to 1640 Portugal was united to Spain, and as a part of the Spanish colonial empire Brazil was naturally exposed to attacks by Spain's enemies. Among these were the Dutch, who had just succeeded in establishing their independence. In 1630 a fleet sent out by the Dutch East India Company captured Pernambuco, the metropolis of the rich sugar growing district in the north. As governor of its new possession the company chose Count Maurice of Nassau-Siegen, a prince of the House of Orange, and perhaps the ablest man in the Netherlands. His statesmanlike programme included the creation of a great colonial empire, rec-

onciliation between Dutch and Portuguese, the grant of religious toleration, and the limited participation of the colonists in the government. Imposing public works were erected in the capital, rechristened Moritzstadt. Distinguished artists and scientists were invited to make known to Europe the resources and beauties of Brazil. But the directors of the company, intent on a policy of greed and gain, refused to support their enlightened governor and he resigned in 1644. A rebellion launched by a wealthy plantation owner, João Fernandes Vieira, proved beyond the power of Maurice's incompetent successors to crush and in 1661 the Dutch renounced all claim to Brazil.

**Expansion and Reforms.**—Reference has already been made to the "Paulistas," as the inhabitants of the captaincy of São Paulo were called. Of part Indian blood, the Paulistas comprised the most enterprising element in colonial Brazil. With the object of securing Indian slaves and discovering mines and precious metals they organized great expeditions into the interior, known as *bandeiras*. At times these expeditions were veritable treks or migrations, in which entire families took part and which lasted for a period of years. Though some of the most remote portions of Brazil were explored by the *bandeiras*, it was not until 1693 that gold deposits were discovered in what is now the State of Minas Geraes. The stampede or gold rush which took place anticipated in many ways the days of '49 in California or those of '51 in Australia. In the hitherto unbroken wilderness towns sprang up as if by magic, while large sections of the littoral were denuded of their inhabitants. The yield of the mines during the 18th century probably exceeded 50,000,000 pounds sterling. Diamonds were discovered in the early 18th century in Minas Geraes and became a royal monopoly. Though many famous stones were found, no figures for the total diamond output are available.

In the latter half of the 18th century the Marquis of Pombal, the famous prime minister of King Joseph I., introduced into Brazil a number of reforms which profoundly affected the social, administrative, and religious life of the colony. The last rights of the donatarios were absorbed by the Crown, the capital was transferred from Bahia to Rio de Janeiro, the Indians were placed on a legal equality with the whites, immigration from the Azores and Madeira was encouraged, two privileged companies were created, a monopoly of the diamond fields was established. The act for which Pombal is best known was the expulsion of the Jesuits from Brazil in 1760. Through their protection of the Indians and their various commercial ventures they had stirred up widespread resentment, and when they attempted to thwart some of Pombal's reforms the all-powerful minister banished them from both Portugal and Brazil with brutal thoroughness. The value of many of Pombal's reforms is more than questionable but it can hardly be denied that they tended on the whole towards the development of the capabilities and resources of Brazil.

#### THE INDEPENDENCE OF BRAZIL

Despite its isolation Brazil could not escape the effects of the revolutionary and Napoleonic epoch in Europe. Brazil is the only instance of a colony becoming the seat of government of its own mother country. When in 1807 Napoleon resolved upon the invasion and conquest of Portugal the prince regent, afterwards Dom John VI., realizing the futility of resistance, decided to take refuge in Brazil. After creating a regency he sailed from the Tagus on Nov. 29, 1807, accompanied by the royal family and a horde of nobles and functionaries. After a short sojourn at Bahia the court arrived safely at Rio on March 7, 1808. The colonists, convinced that a new era had dawned for Brazil, welcomed their sovereign with tremendous enthusiasm. Their expectations were in a measure realized, for the prince regent promptly decreed a number of reforms which radically changed the status of the colony. The harbours of Brazil were opened to the commerce of all friendly nations, thus abolishing the old Portuguese commercial monopoly. A ministry with four portfolios and a council of State were installed in Rio. A supreme court of justice, a court of exchequer and royal treasury, the royal mint, the Bank of Brazil, the royal printing office were established. A royal library, a military academy and medical and law schools

were founded. Industries were encouraged, foreign scholars and artists received a hearty welcome, immigrants were brought in at Government expense. The changed status of Brazil was reflected in the decree of Dec. 16, 1815, by which the Portuguese dominions were designated the "United Kingdom of Portugal, Brazil, and the Algarves." In the year following, the insane queen, Dona Maria I., died, and the prince regent became king with the title of Dom John VI.

**Steps Towards Independence.**—Although Dom John enjoyed a certain degree of personal popularity his government, corrupt and extravagant, aroused much opposition, which was still further increased by the fermentation of liberal ideas produced by the French revolution. In Pernambuco a revolt broke out in 1817, and was put down with difficulty after a republic had been formed which lasted for 90 days. Still more critical was the situation in Lisbon. After the departure of the French, Portugal had been governed by an arbitrary and tyrannical regency. The growing discontent found vent in the revolution of 1820. The regency was swept aside and the *Côrtes*, which had not met for over a century, was summoned for the purpose of drawing up a constitution. The presence of Dom John in Portugal was imperative if the revolutionary movement was to be kept in hand. On April 22, 1821, he appointed his son Dom Pedro regent and two days later set sail for Lisbon. The tasks confronting the young prince were truly formidable. Antagonisms between the Portuguese and Brazilians were becoming increasingly bitter, republican propaganda was active, and, worst of all, Dom Pedro had to face the responsibility of a separation of Brazil from Portugal as a result of the short-sighted policy of the *Côrtes* at Lisbon. The majority of this assembly were in favour of restoring Brazil to her former status of colonial dependence. Without waiting for the Brazilian deputies they proceeded to undo most of the reforms introduced into Brazil by Dom John. Fearful lest Dom Pedro might head a movement for independence, the prince was ordered to return to Europe "in order to complete his political education."

These acts aroused great indignation in Brazil. Supported by the majority of the Brazilians Dom Pedro openly defied the *Côrtes* by his refusal to return to Lisbon. In Jan. 1822 he formed a ministry in which the chief portfolios were held by two distinguished Paulistas, José Bonifácio de Andrada e Silva and his brother, Carlos Antonio. The former, known as the "Patriarch of Independence," was a scholar of European reputation and proved at this critical juncture a tower of strength to the young regent. Events followed rapidly. On June 3 Dom Pedro convoked a legislative and constituent assembly. On Sept. 7, on the plain of Ypiranga, near the city of São Paulo, he solemnly proclaimed the independence of Brazil, and on Dec. 1, 1822, was crowned emperor. With the co-operation of Lord Cochrane, an able British naval officer who had entered Brazilian service, the strong Portuguese garrisons were forced to return to Europe. Before the end of 1823 independence had become an accomplished fact, although Portuguese recognition was not secured until 1825.

#### THE BRAZILIAN EMPIRE (1822-1889)

The first years of Brazilian independence were difficult. The nation was without experience in self-government and the emperor, though able and patriotic, was inclined to be despotic and arbitrary. When the constituent assembly, on which the nation had pinned such high hopes, proved unmanageable Dom Pedro dissolved it in 1823 and sent the Andrada brothers into exile. Fortunately he realized that the days of absolutism were passed; a new and liberal constitution, drawn up by the council of State, was submitted to the municipal councils of the provinces and sworn to with great solemnity by the emperor on March 25, 1824. By this stroke of policy he saved himself and Brazil. The remaining years of Dom Pedro's reign witnessed a growing estrangement between the monarch and his subjects. Parliamentary government was little to the emperor's liking and the opposition generally commanded a majority in the chamber of deputies. Brazil became involved in a disastrous war with Buenos Aires resulting in the loss of the *Provincia Cisplatina* (the present republic of Uruguay). Finally, worn out by attacks from both within and without parlia-

ment, Dom Pedro formally abdicated on April 7, 1831, in favour of the heir apparent, Dom Pedro II., then only five years of age.

**The Regency (1831-1840).**—The next decade proved the most agitated period in Brazilian history. From 1831 to 1835 a triple regency laboured in vain to put down the Civil War in the provinces and check the lawlessness and insubordination in the army. In 1834 an important amendment (the so-called *Acto Adicional*) was made to the Constitution. A measure of decentralization was granted the provinces through the creation of provincial assemblies with considerable local power. Provision was made for a sole regent to be elected for four years. For this office in 1835 an able and energetic priest by the name of Diogo Antonio Feijó was chosen. For two years the regent struggled heroically against the force of disintegration, but he was forced to resign in 1837 and was succeeded by Araújo Lima. As the end of the decade approached sentiment began to crystallize in favour of a declaration of majority of the young Dom Pedro. The Brazilians as a whole, impatient with the regency, hoped to find in the person of the emperor a symbol to which the entire nation might rally. On July 23, 1840, both houses of parliament passed a declaration that Pedro de Alcântara had attained his majority.

The reign of Dom Pedro II., with its duration of practically a half century, constitutes perhaps the most interesting and fruitful epoch in Brazilian history. To an extent true of few monarchies in the 19th century the prestige and progress of the nation were due to the enlightened statesmanship of its ruler. Yet Dom Pedro cared little for the trappings of royalty. Though not without personal distinction he was always simple, modest and democratic. He possessed an insatiable intellectual curiosity and was never more happy than when conversing with scholars. He was generous and magnanimous to a fault. One of his favourite occupations was inspecting schools. He was wont to declare, "If I were not emperor I should like to be a school teacher." Yet this kindly, genial and scholarly ruler took his prerogatives and duties as sovereign with great seriousness and in all matters of first importance he was the final arbiter. According to the constitution of 1824 the emperor had the right to dissolve the chamber of deputies, to select the members of the life senate from triple lists submitted by the province, and to appoint and dismiss ministers of State. That parliamentary life in Brazil was pitched upon such a high plane, that the highest officials in the State generally left office poorer than when they entered it; that the machinery of government functioned smoothly year after year was due in large measure to the tireless vigilance of the emperor.

Though Dom Pedro was by temperament and conviction a pacifist it was hardly to be expected that Brazil should escape controversies with its oft-times turbulent Spanish-American neighbours. Twice was the empire forced to intervene in the affairs of the Platine republics. In 1852 Brazil aided in the overthrow of the Argentine tyrant Rosas (*q.v.*). In the Paraguayan war (*see PARAGUAY*), which lasted from 1865 to 1870, and was caused by the overwhelming vanity and ambition of the Paraguayan dictator López, Brazil played a rôle of major importance. With occasional lapses, the relations between the empire and its continental neighbours and the European Powers were exceedingly cordial. Dom Pedro did much to cement these international friendships and visited Europe in 1876 and 1888 and the United States in 1876.

The outstanding economic and social problems with which the empire had to grapple were connected with the institution of slavery. Partly as a result of pressure from Great Britain Brazil had agreed to abolish the slave trade in 1831, but it was not until 1853 that this odious traffic completely ceased. In the '60s agitation began in favour of the abolition of slavery as such. Dom Pedro was opposed to slavery but he had to reckon with the determined resistance of the slave owners. Finally in 1871 a bill for gradual emancipation, sponsored by the Viscount of Rio Branco, was passed by parliament. The importance of this act lay in the provision that henceforth all children born of slave mothers should be free. But this concession did not satisfy many of the abolitionists, who, led by a brilliant young lawyer and writer, Joaquim Nabuco, demanded that abolition be immediate and complete. In 1883 Nabuco wrote a remarkable book (*O Abolicionismo*), in

which he endeavoured to prove that slavery was poisoning the very life of the nation. The propaganda began to bear fruit. In 1884 Ceará and Amazonas freed their slaves; in 1885 all slaves over 60 years of age were liberated. Finally, complete emancipation without compensation to the owners was decreed on May 13, 1888. Some 700,000 slaves, valued at approximately £40,000,000 were freed.

**The Collapse of the Empire.**—At first sight the overthrow of Dom Pedro seems inexplicable. Under his wise guidance Brazil had made very real progress. His half century of rule had witnessed a growth in population from four to 14 millions, a fourteenfold increase in public revenues and a tenfold increase in the value of the products of the empire. Railroad mileage in 1889 exceeded 5,000; the same year over 100,000 immigrants landed in Brazil. But despite this impressive economic progress there were grave causes of dissatisfaction. Propaganda in favour of a republic, launched in 1871, had gained many recruits. The great landowners who had lost their slaves without compensation withdrew their support from the monarchy. The clergy, another prop of the throne, had been antagonized by the punishment of several recalcitrant bishops. Isabella, the heiress to the throne, and her husband, the Comte d'Eu, were unpopular. Most serious of all, important elements in the army turned against the monarchy, largely because Dom Pedro insisted that they stay out of politics. A conspiracy was hatched by these disgruntled military elements and on Nov. 15, 1889, a revolt of a portion of the army was the signal for the complete collapse of the empire. Dom Pedro formally abdicated and with his family was banished to Europe.

#### THE REPUBLICAN PERIOD

During the next few years Brazil passed through a difficult period of adjustment. The leader of the revolt against Dom Pedro II. was a prominent military figure, Marshal Deodoro da Fonseca. For the next 14 months Brazil was ruled by a military autocracy in which Deodoro, now chief of the Provisional Government, was virtually supreme. Decisions of great importance were reached. Church and State were separated, civil marriage was introduced, and a constituent assembly was summoned which adopted in 1891 a constitution modelled closely on that of the United States. The chief provisions of this instrument are noted elsewhere in this article.

**The Presidencies.**—As president, Deodoro employed the same dictatorial methods that he had followed as head of the provisional régime. He kept in power a most unpopular ministry and was constantly at loggerheads with congress. On Nov. 3, 1891, he forcibly dissolved this body and proclaimed himself dictator. But opposition to this *coup d'état* was so widespread that on Nov. 23, 1891, he felt constrained to resign in favour of the vice-president, Marshal Floriano Peixoto. But Floriano, likewise one of the conspirators against Dom Pedro, differed little in his methods of government from his predecessor. Of the meaning of constitutionalism in the strict sense of the term he had scant understanding. The growing opposition to Floriano finally culminated in 1893 in a naval revolt and military uprising that were put down the following year only with the greatest difficulty.

The vast majority of the Brazilians are naturally averse to militarism, especially when it is accompanied by violence and corruption. The advent, therefore, of a civilian as president was hailed with undisguised relief. Prudente de Moraes Barros, who assumed office in 1894, was a distinguished lawyer of São Paulo and a republican of long standing. Though his intentions were excellent and his ability and honesty unquestioned, his administration was rendered largely sterile through the opposition of the disgruntled military elements and the necessity of putting down a rebellion of the ignorant and fanatical population in the hinterland of Bahia. His successor Manuel Ferraz de Campos Salles (1898-1902), former president of the State of São Paulo, is chiefly remembered for his striking success in saving Brazil from the financial collapse threatened by the orgy of extravagance, inflated currency and speculation which had followed the overthrow of the monarchy. While still president-elect, Campos Salles in 1898 negotiated through the Rothschilds a funding loan of

£10,000,000, interest on which was to be suspended for three years and amortization payments for ten. Thanks to the able and economical administration of Campos Salles and the marvellous recuperative power of the country, the credit and finances of Brazil were again placed on a sound foundation. Francisco de Paula Rodrigues Alves (1902-06), likewise a Paulista, is generally regarded as Brazil's ablest civilian president. During his term of office the capital was transformed into one of the world's most beautiful cities. Under the direction of the distinguished physician and scientist, Dr. Oswaldo Cruz, Rio was completely freed from the scourge of yellow fever. As noted at the beginning of the present article some of Brazil's most thorny boundary controversies were settled during the presidencies of Campos Salles and Rodrigues Alves by the able minister of foreign affairs, the Baron of Rio Branco.

The history of Brazil during the two decades, 1906-26 must be summarized very briefly. President Affonso Penna (1906-09) took an important step towards the stabilization of the exchange through the creation of the so-called Caixa de Conversão, or Bank of Conversion, whose function was to redeem inconvertible paper currency through the issue of convertible notes secured through the deposit of gold. Unfortunately this project had to be abandoned on the outbreak of the World War. Dr. Penna died in 1909 and was succeeded by the vice-president, Dr. Nilo Peçanha. The campaign of 1910 was fought with great bitterness. The official candidate, Marshal Hermes da Fonseca, the nephew of Deodoro da Fonseca, was opposed by a civilian, Dr. Ruy Barbosa, a noted lawyer and publicist, and the most eloquent public speaker in Brazil. Though the conviction was general that Dr. Barbosa had received a majority of the votes cast, the official machine easily secured the election of Hermes da Fonseca. The administration of the new president (1910-14) represented a step backward in the political life of Brazil. The high standards set by the first three civilian executives were largely abandoned.

**Brazil and the World War.**—Happily a change for the better came with the election of Dr. Wenceslau Braz (1914-18), a former governor of Minas Geraes. The administration of President Braz is indissolubly associated with Brazil's reaction to and participation in the World War. From the outset of the struggle the sympathies of the majority of the Brazilians inclined toward the Allies. On April 11, 1917, Brazil broke off relations with Germany following the torpedoing of the steamer *Paraná* off the coast of France. On June 1 Brazil revoked its decree of neutrality in the war between Germany and the United States as a mark of "continental solidarity" and friendship with the United States. Following the sinking of more Brazilian ships war was declared on Oct. 26. Brazil's participation in the war was confined to the despatch of a part of its fleet to European waters and the sending of a medical mission and a number of aviators to the western front. Brazil's chief contribution, however, was the placing of its food supplies and other resources unreservedly at the disposal of the Allies and the United States. Brazil participated in the Peace Conference and was given a temporary seat on the Council of the League of Nations.

**Brazil Since the World War.**—In the election of 1918 a new precedent was established in Brazilian political life by the reelection of Rodrigues Alves. Unfortunately the new executive was too ill to accept office and died on Jan. 16, 1919. In the new election, held in April, the successful candidate was Dr. Epitácio da Silva Pessoa, a lawyer of note, and head of the Brazilian delegation at the Versailles Peace Conference. His presidency, coinciding with the wave of post-war prosperity, was an era of reckless expenditures accompanied by an immense increase in both the internal and foreign debt of Brazil. Large sums were absorbed by the Brazilian Centenary Exposition, which was celebrated with great brilliancy in 1922. The presidency of Dr. Arthur Bernardes (1922-26) was beset with difficulties. The collapse of the post-war boom found Brazil in financial extremities. The new executive endeavoured to carry out a policy of strict economy. Governmental expenses were cut down, the prosecution of costly public works was postponed, new sources of revenue, such as the income tax, were created. Unhappily the success of this programme of re-

trenchment and reform was compromised by a dangerous flare up of militarism. In the closing weeks of Dr. Pessôa's administration the political militarists led by Hermes da Fonseca made a desperate but fruitless effort to prevent the inauguration of Dr. Bernardes. In the summer of 1924 a serious military revolt engineered by the same disaffected elements that had supported the earlier revolt broke out in the city of São Paulo. But the overwhelming majority of the Brazilians rallied to the support of the Government and the uprising was put down, though not until after many lives had been lost and much property damage done. In the domain of foreign affairs Dr. Bernardes' administration was responsible for the announcement (June 13, 1926) that Brazil would withdraw from the League of Nations on the ground that Brazil had not been accorded a permanent seat on the Council. The election of 1926—an almost unprecedented circumstance in Brazil—was not only uncontested but evoked the enthusiastic approval of practically the entire nation. Dr. Washington Luis Pereira de Souza, the new executive, had been minister of justice under two previous administrations, and had achieved a brilliant record as president of the State of São Paulo (1920–24). His elevation to the presidency was hailed as signifying the dawn of a better era.

#### ART, SCIENCE AND LITERATURE

**Painting, Sculpture and Music.**—The Brazilian people have the natural taste for art, music and literature so common among the Latin nations of the Old World. As early as 1816 Dom John VI. invited a company of distinguished French painters, headed by Lebreton, the secretary of the Ecole des Beaux Arts of Paris to take up their residence in Rio de Janeiro and to implant in Brazil the best French artistic traditions. Dom Pedro II. was a liberal patron of art and early in his reign was founded the Academia de Bellas Artes, now known as the Escola Nacional de Bellas Artes. Free instruction in the fine arts is given in this school. Among Brazil's better known painters should be mentioned Pedro Americo de Figueiredo, who specialized in historical and allegorical subjects. In sculpture Rodolpho Bernadelli has done excellent work. A conservatory of music was established as early as 1841. The composer Carlos Gomez (1839–96) enjoyed world-wide fame, his opera, *O Guarany*, having been produced in most of the European capitals. Alberto Nepomuceno (1846– ) has also written a number of operas which have achieved success both in Brazil and Europe.

**Science.**—Until recent years scientific exploration and investigation had been largely conducted by foreigners. Of the scholars who were both explorers and scientists may be mentioned W. L. von Eschwege, J. B. von Spix, C. F. von Martins, Prince Max zu Neuwied, Karl von den Steinen, A. de St. Hilaire, Louis Agassiz and the English botanists A. R. Wallace and H. W. Bates. Geological investigations of immense and lasting value have been carried on by the American scientists Charles Frederick Hartt, Orville A. Derby and John Casper Branner. Among Brazilian scientists may be noted the geographers Homen de Mello, Belfort Mattos and Delgado de Carvalho, and the botanist João Barbosa Rodrigues. Scientific explorations of great value have been performed by Gen. Mariano da Silva Rondon. Brazilians have achieved notable success in the study of tropical diseases. Dr. Oswaldo Cruz, as noted elsewhere, banished yellow fever from the capital. Dr. Vital Brasil, director of the Butantan Institute near São Paulo has been remarkably successful in discovering serums against the bites of venomous reptiles. The Instituto Oswaldo Cruz near Rio and the Pasteur Institute at São Paulo afford both Brazilians and foreigners opportunities for the study of tropical diseases.

**Literature.**—Down to the middle of the 18th century Brazilian literature was naturally dominated by Portugal, for Brazil was intellectually as well as economically a colony. The 80 years from 1750 to 1830 may be regarded as a period of transition, during which Brazilian literature gradually acquired an autonomous character. Between 1830 and 1870 came a period of romantic transformation, when French influence was distinctly in the ascendant. Since 1870 there has come into existence a new school which, distinctly hospitable to foreign influences, is in the broadest sense national.

The three most famous writers of the colonial and transitional periods are Gregorio de Mattos Guerra, Basilio da Gama and Santa Rita Durão. The era of romantic transformation is represented by Brazil's greatest lyric poet, Gonçalves Dias. The romantic movement also produced the Brazilian novel. Here the outstanding figures are José de Alencar, who glorified the Brazilian Indians (*Guarany* and *Iracema*) and Escagnolle de Taunay, whose novel *Innocencia* has been translated into six foreign languages including the Japanese. The reaction in France against the romantic school had its counterpart in Brazil. Parnassianism included among its votaries the poets Theophilo Dias, Raymundo Correia, Alberto de Oliveira and Olavo Bilac. Naturalism is represented by the novelists Machado de Assis, Aluzio de Azevedo, Julio Ribeiro and Raul Pompeia. Later developments do not readily lend themselves to analysis. In general the emphasis has shifted to national and regional themes. Graça Aranha, in his novel *Chacaranã*, has chosen as his subject the Brazilian melting-pot. Euclides da Cunha, in *Os Sertões*, has produced a poignant and arresting study of the hinterland (*sertões*) of Bahia. Coelho Netto is a neo-romanticist who has drawn upon Brazilian history and tradition for the plots of his many novels. José Veríssimo, Monteiro Lobato, and Sylvio Romero are brilliant essayists. The last-named writer is also the author of the standard history of Brazilian literature.

In historical literature Brazil has produced a number of writers of high standing. Francisco Adolpho Varnhagen (Visconde de Porto Seguro) is the author of the most authoritative history of the colonial period. João Manoel Pereira da Silva has treated especially the critical years from 1822 to 1840. João Capistrano de Abreu has produced some short historical studies of great merit. Joaquim Nabuco's magisterial biography of his father, Nabuco de Araujo, is really a history of the reign of Dom Pedro II. Manoel de Oliveira Lima has covered every epoch of Brazilian history. His most notable single work is the history of Dom John's residence in Brazil (1808–21).

**BIBLIOGRAPHY.**—The most satisfactory general work on Brazil is by H. G. James, *Brazil after a Century of Independence* (1925); Pierre Denis, *Brazil* (1913) is scholarly but slightly antiquated; J. C. Oakenfull, *Brazil, Past, Present and Future* (1919) is an extensive compendium of facts rather poorly organized. The following three works are essentially journalistic in style but contain much material of interest: L. E. Elliott, *Brazil, To-day and To-morrow* (1919), Roy Nash, *The Conquest of Brazil* (1926) and C. S. Cooper, *The Brazilians and their Country* (1917); a number of books dealing with all or parts of South America include valuable sections on Brazil; such are James Bryce, *South America, Observations and Impressions* (1920), H. G. James and P. A. Martin, *The Republics of Latin America* (1925), Georges Clemenceau, *South America of To-day* (1911), C. Reginald Enoch, *The Republics of Central and South America* (1913), H. C. Franck, *Working North from Patagonia* (1921).

**History.**—There is no general history of Brazil in English. Authoritative brief accounts may be found in James and Martin, *The Republics of Latin America*, W. S. Robertson, *History of the Latin American Nations* (1922) and T. C. Dawson, *South American Republics* (1910). The first two of these works contain detailed bibliographies. Important works dealing with specific periods are Robert Southey, *The History of Brazil* (1810–1819. Colonial period), John Armitage, *The History of Brazil from 1818 to 1831* (1836. A continuation of Southey), D. P. Kidder and J. C. Fletcher, *Brazil and the Brazilians* (1879). This last work is a fascinating account of conditions under the empire. C. E. Akers, *A History of South America, 1854–1900* (1912), has some excellent chapters on the period covered. Practically all of the works of Brazilian historians appear only in Portuguese. Of the exceptions the most important are a scholarly survey of the whole field by M. de Oliveira Lima, *Formation Historique de la Nationalité brésilienne* (1911) and an able biography of Dom Pedro II. by B. Mossé, *Dom Pedro II., Empereur du Brésil* (1889). The following works include sections dealing with the international relations of Brazil: W. R. Manning, *Diplomatic Correspondence of the United States concerning the Independence of the Latin-American Nations* (1925), G. H. Stuart, *The United States and Latin America* (1928), P. A. Martin, *Latin America and the War* (Baltimore, 1925). The best work on the government of Brazil is H. G. James, *The Constitutional System of Brazil* (1923). Briefer accounts will be found in James and Martin, *Republics of Latin America*, and Bryce, *South America*.

**Geography, climate, resources, etc.**—The sections on Brazil in the works of such writers as E. Reclus, *Nouvelle Géographie Universelle* (1875–94), A. H. Keane, *Central and South America* (1909) and Wilhelm Sievers, *Süd und Mittelamerika* (Leipzig, 1903), though

somewhat antiquated are still valuable. E. C. Buley has written two useful handbooks, *South Brazil*, and *North Brazil* (1914). The two works of Pierre Walle, *Au Brésil du Rio São Francisco à l'Amazonie* and *Au Brésil de l'Uruguay au Rio São Francisco*, contain a wealth of economic and other data. Recent geographies containing admirable chapters on Brazil are R. H. Whitbeck, *Economic Geography of South America* (1926) and E. W. Shanahan, *South America: an Economic and Regional Geography* (1927). The best work on climate and rainfall is that of C. M. Delgado de Carvalho, *Météorologie du Brésil* (1917). The *Reports on the Economic and Financial Conditions in Brazil*, prepared by Ernest Hambloch annually, and issued by the Department of Overseas Trade, contain important data.

See also Pierre Denis, "Amérique du Sud," in *Géographie Universelle*, vol. xv., pt. ii., ed. De la Blanche et Gallois (Paris, 1927) for valuable facts.

Literature, fine arts, etc.:—The best work in English on Brazilian Literature is by Isaac Goldberg, *Brazilian Literature* (1922). Victor Oban, *Le Brésil Littéraire*, has written an interesting anthology. A brief account of Brazilian painting and music is given by Marie R. Wright, *The New Brazil* (Philadelphia, 1907). (P. A. M.)

**BRAZIL** or **BRASIL**, a legendary island in the Atlantic Ocean. The name signifies the red dye-woods used in the middle ages, and *Insulae purpurariae* are mentioned by Pliny. It first appears as the *I. de Bazi*, one of the larger islands of the Azores, in the Venetian map of Andrea Bianco (1436). When this group became better known and was colonized, this island was renamed Terceira. Probably the familiar existence of "Brazil" as a geographical name led to its bestowal upon the vast region of South America, which was found to supply dye-woods. But the "Island of Brazil" retained its place in mid-ocean, some hundred miles to the west of Ireland, both in the traditions of the fore-castle and in charts. In J. Purdy's *General Chart of the Atlantic* "corrected to 1830" the "Brazil Rock (high)" is marked with no indication of doubt, in 51° 10' N. and 15° 50' W. In a chart of currents, dated 1853, A. G. Findlay gives the name, but in his 12th edition of Purdy's *Memoir Descriptive and Explanatory of the N. Atlantic Ocean* (1865), the existence of Brazil and some other legendary islands is briefly discussed and rejected. (See also ATLANTIS.)

**BRAZIL**, a city in the western part of Indiana, U.S.A., 16m. N. by E. of Terre Haute; the county seat of Clay county. It is on Federal highway 40, and is served by the Central Indiana, the Chicago and Eastern Illinois, the Cincinnati, Indianapolis and Western, and the Pennsylvania railways. The population in 1930 was 8,744. It is in the heart of deposits of clay and shale, and of the "Brazil Block district" of the Indiana coal-fields, so called because this coal breaks naturally into almost perfect rectangular blocks. The manufactures include sewer-pipe, bricks, furniture, tin cans, boilers, engines, mine-fans, and mining machinery. The first settlement here was made in 1844. The town was incorporated in 1866, and chartered as a city in 1873.

**BRAZIL NUTS**, the seeds of a large tree (*Bertholletia excelsa*) of the lecythis family (Lecythidaceae), which grows throughout tropical America. The tree attains a height of 130ft., and has a globular fruit, with a diameter of five or six inches, consisting of a thick hard woody shell, within which are packed the seeds which constitute the so-called nuts of commerce. The seeds are triangular in form, having a hard woody testa enclosing the "kernel"; and of these each fruit contains from 18 to 25.

**BRAZIL WOOD**, a dye wood obtained from West Indian and South American trees belonging to the genera *Caesalpinia* and *Peltophorum* of the family Leguminosae. There are several woods, commercially distinguished as Brazil wood, Nicaragua or Peach wood, Pernambuco wood and Lima wood, each of which has a different commercial value, although the tinctorial principle they yield is similar. Brazil wood is imported for the use of dyers in billets of large size, and is a dense compact wood reddish brown in colour, bright when freshly cut, but becoming dull on exposure. The colouring-matter of Brazil wood, brazilin,  $C_{12}H_{14}O_6$ , crystallizes with  $1\frac{1}{2} H_2O$ , and is soluble in water; it is extracted for use by infusion or decoction of the coarsely powdered wood. When freshly prepared the extract is yellowish; but by contact with the air, or the addition of an alkaline solution, it develops a brick-red colour. This is due to the formation of brazilein,  $C_{12}H_{12}O_6 \cdot H_2O$ , which is the colouring matter used by the dyer.

**BRAZING AND SOLDERING**, the process of uniting two metallic surfaces together by means of a fused metallic material joining them (cf. WELDING); usually distinguished as hard soldering or soft soldering. In each the melting temperature of the solder is lower than that of the metal or alloy to be united. This is more markedly so in the case of soft solder, which makes a joint without producing discoloration by heat, an important advantage in tinware. Hard solder, or brazing spelter, makes more intimate union with the work, hence the result is stronger. But soft solder is quite satisfactory for tinware, lead, plumbing, pewter, Britannia metal, while brass, copper, iron and steel may be soldered for some purposes, or brazed together when greater strength or resistance to heat becomes essential; aluminium is not so simple to solder as the other materials. There are a great many recipes for the compositions of solders, according to the class of material to be joined, and numerous types of joints. A flux is always necessary to ensure chemical cleanliness.

For brazing, heat must be obtained from a clear fire, a blow-pipe or blast flame, the grip of red-hot tongs, or by having the spelter molten in a bath. The flux, such as borax, is applied while the joint is hot, and the spelter put on in convenient shape—thin sheet, strip, wire, or small lumps, which melt and run freely between the faces. A handy form of brazing medium is sold combined with the flux, pieces being broken off and used without the need for separate fluxing. If the flow is not certain to spread properly between a joint, notwithstanding a jarring action being given to help matters, it is preferable to sandwich the spelter in, and draw the parts together by means of wire bound round or with the tongs, while clamps are utilized for some articles, such as the thinned ends of band-saws which are held overlapping in exact position during the process. Dipping into a molten bath affords the best mode of even penetration for some joints, notably those of cycle frames.

Should parts not fit together rigidly, or extra strength be required, additional resistance to bending or twisting stresses can be gained by putting pegs through a joint, inserting liners in tubular joints, or serrating faces so that the spelter runs into the grooves and forms so many keys. Rather thin metal, such as in copper-pipes and fittings made for ships, distilleries, breweries, etc., is brazed up with "clamped" joints for extra security and resistance to the internal pressure of steam or other fluid. One edge is left plain, the other has notches cut, as evidenced from the detail in fig. 1, and each alternate "clamp" is lifted slightly so as to enable the other plain edge to be slipped in. After hammering or closing the joint neatly, it is jarred to bring about a slight freedom for the spelter to flow into. The employment of a solu-

FIG. 1.—THE NOTCHED CLAMP JOINT, USED EXTENSIVELY IN COPPER-SMITHING

tion of borax and water as a flux also ensures perfect preparation of the faces. Joints are also thinned, as well as clamped, in order that the total thickness shall not much exceed that of the sheet, if at all. The other view shows a copper three-way or T-piece brazed up with clamped joints. Annealing has sometimes to be done, after brazing, and hammering a joint neatly, to obviate risk of cracking.

An example of support afforded in a joint appears in fig. 2, in which case a great force tends to tear the parts asunder. This is a tool used in a metal-turning lathe, and made up with a long shank of mild or of low-carbon steel, to which is brazed a tip of the expensive high-speed cutting steel. This rests on a ledge on

the shank, and is often additionally locked by fitting it on a vee surface instead of flat, so as to resist side movement. The brazing compound is sandwiched in, the parts bound with brass wire, and heat applied in the fire or gas-blast.

Electric brazing is performed by gripping the parts in the electrodes of an electric welder type of machine. The spelter and flux are applied, and the current switched on, raising the joint to a sufficient heat for fusion.

The lower temperature that suffices for soft soldering rather simplifies the methods. A copper soldering-bolt may be pressed

FIG. 2.—BRAZING A HIGH-SPEED STEEL TIP ON TO A LATHE TOOL

on the work to cause the solder to run, or drawn along to make it flow from a stick in the required direction. The blowpipe gives a delicate and perfectly controllable flow, and small joints are preferably made with its help. Sweating is a convenient mode of uniting some specimens, heat being applied throughout the area. Pouring from a ladle is done when a considerable quantity of solder must be applied; this is so in regard to water-pipes having to withstand a good pressure.

Support has to be given to some objects which do not retain their relationships naturally, including certain frames, and pipes, complicated by overhanging details. Clay, charcoal blocks, or screw clamps variously take care of these subjects; fig. 3 represents a divided clamp which locates pipes in their setting for a wiped joint. If faces are not bright, they must be filed, ground, scraped or shaved, or polished with emery-cloth, and a flux is requisite to clear away oxide. Fluxes include rosin, sal-ammoniac, tallow, chloride of zinc solution (killed spirits), or one of the proprietary pastes sold in tins. "Tinning" is a process required for two reasons: to prepare faces in iron, copper, and brass ready for adhesion of the solder, and to cover the nose of the soldering-iron so that oxidation will not occur while it is being used. A flux is applied to the cleaned metal in either instance, and the solder allowed to run thoroughly.

Although as a rule a thin film of solder is all that is necessary to give strength to a joint, the wiped joint of the plumber con-

FIG. 3.—METHOD OF HOLDING PIPES IN POSITION FOR MAKING A JOINT

stitutes an exception. One end of a pipe is opened out with a conical bobbin driven in, the matching end is coned (fig. 3) and the surfaces shaved clean. Pouring is done from a ladle, using a thick cloth to control the plastic mass and wipe it into a neat shape. Blacklead may be rubbed on surfaces to which solder must not adhere, or a mixture termed "soil" or "smudge."

The tinsmith uses soldering machines to hold cans, etc., in certain attitudes, while being soldered, while in the large canning factories for fish, fruit, or vegetables automatic machines are installed, which pass tins along by conveyors, and the fluxing and

soldering are effected with great rapidity. Some will do 40,000 or more cans per ten-hour day, that is 80,000 ends.

The following give a few of the very many solders in use:—

|                   |   |
|-------------------|---|
| Coarse Solder     | Lead 3 parts, Tin 1 part  |
| Plumber's Solder  | Lead 2 parts, Tin 1 part  |
| Fine Solder       | Lead 1 part, Tin 1 part   |
| Tinman's Solder   | Lead 2 parts, Tin 3 parts   |
| Ditto, fine       | Lead 1 part, Tin 2 parts  |
| Pewterer's Solder | Lead 4 parts, Tin 3 parts   |
| Bismuth Solder    | Lead 1 part, Tin 1 part, Bismuth 1 part   |
| Hard Solders      | Copper 2, Zinc 1; Copper 1, Zinc 1; Copper 3, Zinc 1.   |
| For Silver        | Copper 1, Brass 1, Silver 19; Brass 1, Silver 2.  |
| For Gold          | Gold, silver, and copper or brass in varying proportions according to the carat of the gold to be soldered. |

(F. H.)

**BRAZZA, PIERRE PAUL FRANÇOIS CAMILLE SAVORGNAN DE, COUNT** (1852-1905), French explorer and administrator, founder of French Congo, was born on board ship in the harbour of Rio de Janeiro on Jan. 26, 1852. He was of Italian parentage, the family name being de Brazza Savorgnani. Through the astronomer Secchi he was sent to the Jesuit college in Paris, and in 1868 obtained authorization to enter as a foreigner the marine college at Brest. In the Franco-Prussian War of 1870-71 he took part in the operations of the French fleet. In 1874 when the warship on which he was serving was in the Gabun, Alfred Marche and the marquis de Compiègne arrived at Libreville from an expedition in the lower Ogowe district. Interested in the reports of these travellers, de Brazza conceived the idea of exploring the Ogowe, which he thought might prove to be the lower course of the Lualaba, a river then recently discovered by David Livingstone. Having meantime been naturalized as a Frenchman, de Brazza in 1875 obtained permission to undertake his African scheme, and with the naval doctor, Noel Ballay, he explored the Ogowe river. Penetrating beyond the basin of that river, he discovered the Alima and Likona, but did not descend either stream. Thence turning northwards the travellers eventually regained the coast at the end of Nov. 1878, having left Paris in Aug. 1875. On arrival in Paris, de Brazza learned of the navigation of the Congo by H. M. Stanley, and recognized that the rivers he had discovered were affluents of that stream.

De Brazza was anxious to obtain for France some part of the Congo. The French Ministry, however, determined to utilize his energies in the Niger basin. Their attention had been drawn to the Niger through the formation of the United African Company by Sir George Goldie (then Mr. Goldie Taubman) in July 1879, Goldie's object being to secure Nigeria for Great Britain. A new expedition was fitted out, and de Brazza left Paris at the end of 1879 with orders to go to the Niger, make treaties, and plant French flags. When on the point of sailing from Lisbon he received a telegram cancelling these instructions and altering his destination to the Congo. This was a decision of great moment. Had the Nigerian policy of France been maintained the International African Association (afterwards the Congo Free State) would have had a clear field on the Congo, while the young British company might have been crushed out by French opposition; so that the two great basins of the Niger and the Congo would have had a vastly different history.

Acting on his new instructions, de Brazza, who was again accompanied by Ballay, reached the Gabun early in 1880. Rapidly ascending the Ogowe he founded the station of Franceville on the upper waters of that river and pushed on to the Congo at Stanley Pool, where Brazzaville was subsequently founded. With Makoko, chief of the Bateke tribe, de Brazza concluded treaties in Sept. and Oct. 1880, placing the country under French protection. With these treaties in his possession Brazza proceeded down the Congo, and at Isangila on Nov. 7 met Stanley, who was working his way upstream concluding treaties with the chiefs on behalf of the International African Association. De Brazza spent the next eighteen months exploring the hinterland of the Gabun, and returned to France in June 1882. The ratification by the French chambers in the following November of the treaties with Makoko (described by Stanley as worthless pieces of paper) committed France to the action of her agent.

Furnished with funds by the French Government, de Brazza returned in 1883 to the Congo to open up the new colony, of which he was named commissioner-general in 1886. This post he held until Jan. 1898, when he was recalled. During his period of office the work of exploration was systematically carried out by numerous expeditions which he organized. De Brazza's administration was severely criticized; but that its comparative failure was largely due to inadequate support from the home authorities was recognized in the grant to him in 1902 of a pension by the chambers. Both as explorer and administrator his dealings with the natives were marked by consideration, kindness and patience, and he received the title of "Father of the Slaves." His efforts to connect the upper Congo with the Atlantic by a railway through French territory showed that he understood the chief economic needs of the colony. After seven years of retirement in France de Brazza accepted, in Feb. 1905, a mission to investigate charges of cruelty to natives brought against officials of the Congo colony. Having concluded his enquiry he sailed for France, but died at Dakar, Senegal, on Sept. 4, 1905. His body was taken to Paris for burial, but in 1908 was reinterred at Algiers.

See D. Neuville et Ch. Bréard, *Les Voyages de Savorgnan de Brazza, Ogoûé et Congo, 1875-1882* (1884), and *Conférences et lettres de P. Savorgnan de Brazza sur ses trois explorations dans l'ouest africain de 1875 à 1886* (1887); A. J. Wauters, "Savorgnan de Brazza et la conquête du Congo français," in *Le Mouvement géographique*, vol. xxii., No. 39 (Brussels, 1905). Giacomo or Jacques de Brazza (1850-83), a younger brother of Savorgnan and one of the men he employed in the work of exploration, published, in collaboration with his companion A. Pecile, *Tre Anni e mezzo nella regione del Congo e dell'Ogoûé* (1887). (G. T. G.)

**BRAZZA** (Serbo-Croatian Brač), an island in the Adriatic sea, forming part of Dalmatia, Yugoslavia. Pop. (1921) 19,326. With an area of about 200 sq.m. Brazza is the largest of the Dalmatian islands; it is also fertile and the most thickly populated. Though rugged and mountainous, it yields an abundance of olives, figs, almonds, saffron, and chrysanthemums from which an insect powder is produced, as well as wines of good quality. The corn crop, however, barely suffices for three months' food. Other local industries are fishing, silkworm-rearing, stone, slate and marble quarrying, and the working of asphalt deposits. The most important among the 26 villages on the island is Milna (Pop. [1921] 3,206), which has a good harbour, and is provided with shipwrights' wharves, where coasting vessels are built. It has also a steam flourmill. There are many fine churches and substantial stone houses. The island has been dominated in turn by the pirates of Almissa, by Ragusa, Venice, the Holy Roman Empire, Hungary, Bosnia, Russia and Austria, with one brief period of autonomy. In 1918 it was incorporated with Yugoslavia.

**BREACH**, in general, a breaking or an opening made by breaking; in law, the infringement of a right or the violation of an obligation or duty. The word is used in various phrases: *breach of close*, the unlawful entry upon another person's land (see *TRESPASS*); *breach of covenant or contract*, the non-fulfilment of an agreement either to do or not to do some act (see *DAMAGES*); *breach of the peace*, a disturbance of the public order (see *PEACE*, *BREACH OF*); *pound-breach*, the taking by force out of a pound things lawfully impounded (see *POUND*); *breach of promise of marriage*, the non-fulfilment of a contract mutually entered into by a man and a woman that they will marry each other (see *MARRIAGE*); *breach of trust*, any deviation by a trustee from the duty imposed upon him by the instrument creating the trust (q.v.). In military science, a break or opening in the wall of a fortress, caused by bombardment by the artillery of the besieger or by his mines, and utilized by his storming parties in the assault. Also applied, loosely, to a penetration of an entrenched defensive position.

**BREACH OF THE PEACE** is any act or conduct bringing about a disturbance of the public peace or tranquillity. (See also *AFFRAY* and *RIOT*.) The matter generally becomes important before any substantive breach or offence is committed, for in such a case, where a breach of the peace is threatened, justices have power to intervene by binding over the offender. They have a like power for abusive language tending to a breach of the peace.

At common law and under the statute of Edward III., and by the commission of the peace granted to justices, recognizances may be required on the part of the accused and also sureties for good behaviour. Apparently a peer of the realm cannot be bound over by justices but only by the High Court. (See also *ARREST*.)

**BREAD.** The name given to the staple food-product prepared by the baking of flour. Bread baking, or at any rate the preparation of cakes from flour or parched grain by means of heat, is one of the most ancient of human arts. At Wangen and Robenhausen have been found the calcined remains of cakes made from coarsely-ground grain in Swiss lake-dwellings that date back to the Stone Age. The cakes were made of different kinds of grain, barley and one-grained wheat (*Triticum monococcum*) being among the ingredients. This bread was made, not from fine meal, but from grain crushed between hard surfaces. (See *FLOUR AND FLOUR MANUFACTURE*.) Perhaps the earliest form of bread, if that word may be used, was prepared from acorns and beech nuts. To this day a cake prepared from crushed acorns is eaten by the Indians of the Pacific slopes. The flour extracted from acorns is bitter and unfit to eat till it has been thoroughly soaked in boiling water. The saturated flour is squeezed into a cake and dried in the sun. Pliny speaks of a similar crude process in connection with wheat; the grain was evidently pounded and the crushed remnant soaked into a pulp, then made into a cake and dried in the sun. Virgil (*Georgics*, i. 267) refers to the husbandman first toasting and then crushing his grain between stones: *Nunc torrete igni fruges, nunc frangite saxo*.

How did the lake-dwellers bake their cakes of bruised grain? Probably the dough was laid on a flat or convex-shaped stone, which was heated, while the cake was covered with hot ashes. Stones have been found among prehistoric remains which were apparently used for this purpose. In ancient Egyptian tombs cakes of durra have been found, of concave shape, suggesting the use of such baking-slabs; here the cake was evidently prepared from coarsely-cracked grain. In primitive times milling and baking were twin arts. The housewife crushed or ground the grain and prepared the bread or cakes. Professor Maspero says that an oven for baking bread was to be found in the courtyard of every house in Chaldaea; close by were kept the grinding stones. That bread prepared by means of leaven was known in the days of the patriarchs may be fairly inferred from the passage in Gen. iii., where it is said of Lot that he "made a feast, and did bake unleavened bread." Whether the shewbread of the Jewish tabernacle was leavened is an open question, but it is significant that the Pass-over cakes eaten by Jews to-day, known as matzos, are innocent of leaven. Made from flour and water only, they are about 12 in. in diameter, and resemble water biscuits.

**The White Bread of Egypt.**—The ancient Egyptians carried the art of baking to high perfection. Herodotus remarks of them, "dough they knead with their feet, but clay with their hands." The practice of using the feet for dough kneading, however repulsive, long persisted in Scotland, if indeed it is yet defunct. The Egyptians used for their bread, wheat, spelt, barley and durra. It is certain that even in ancient Egypt white bread made from wheat was used by the rich. The form of the bread is revealed by ancient monuments. A common shape was a small, round loaf, something like the muffin of to-day. Other loaves were elongated rolls, and curiously enough were sprinkled on the top with seeds like modern Vienna bread.

The history of baking in classical Greece and Italy can be clearly traced. Athenaeus in his *Deipnosophists* minutely describes many different kinds of bread, which may be assumed to have been currently used in Greece. According to Pliny (*Nat. Hist.* xviii. II. s. 28) Rome had no public bakers till after the war with Perseus (171-168 B.C.). That long after public bake-houses came into use the Romans and other urban dwellers in Italy continued to make a great deal of bread at home is certain. In Pompeii several private houses had their own mill and bake-house. That city must also have possessed bakers by trade, as loaves of bread have been found, round in form, and stamped with the maker's name, possibly to fix responsibility for weight and purity. In the time of the republic, public bakehouses were

under the control of the aediles. Grain was delivered to the public granaries by the *Saccarii*, while another body called *Catabolenses* distributed the grain to the bakers. The latter were known as *Pistores* or "pounders," a reminiscence of the primitive time when grain was pounded by a pestle in a mortar. Slaves were largely employed in the irksome work of grinding, and when Constantine abolished slavery the staff of the *Pistrinae* was largely recruited from criminals. The emperor Trajan incorporated about A.D. 100 the college of *Pistores* (millers and bakers), but its members were employers, not operatives. The work of a bakery is depicted in a set of bas-reliefs on the tomb of a master *pistor* named Eurysaces, who flourished about a century before the foundation of the college.

**Regulation of Sale.**—In the middle ages bakers were subjected to special regulations in all European lands. These regulations were supposed to be conceived in the interests of bread consumers, and no doubt were intended to secure fair dealing on the part of bread vendors. The legislators appear, however, to have been unduly biased against the baker, who was often beset by harassing restrictions. Bakers were formed into guilds, which were under the control, not only of their own officials, but of the municipality. In London the bakers formed a brotherhood as early as 1155, and were incorporated in 1307. There were two distinct corporate bodies concerned with bread making, the Company of White Bakers and the Company of Brown Bakers; these were nominally united in 1509, but the union did not become complete till the middle of the 17th century. In Austria, bakers who offended against police regulations respecting the sale of bread were liable, until comparatively recent times, to fine, imprisonment and even corporal punishment. In Turkey the lot of the baker was hard. Baron de Tott, writing of Constantinople in the 18th century, says that it was usual, when bread went to famine prices, to hang a baker or two, which was promptly done. A barbarous punishment, inflicted in Turkey and in Egypt on bakers who sold light or adulterated bread, consisted in nailing the culprit by his ear to the door-post of his shop. In France a decree of 1863 relieved bakers from many of the restrictions under which they previously suffered, but it did not touch the powers of the municipalities to regulate the quality and sale of bread. It left them the right conferred in 1791, to enforce the *taxe du pain*, the object of which was to prevent bakers from increasing the price of bread beyond a point justified by the price of the raw materials; but the right was exercised on their own responsibility, subject to appeal to higher authorities, and by a circular issued in 1863 they were invited to abolish this *taxe officielle*. In places where it exists it is fixed every week or fortnight, according to the average price of grain in the local markets.

In England an act of parliament was passed in 1266 for regulating the price of bread by a public assize, and that system continued in operation till 1822 in the case of the city of London, and till 1836 for the rest of the country. The price of bread was determined by adding a certain sum to the price of every quarter of flour, to cover the baker's expenses and profit; and for the sum so arrived at tradesmen were required to bake and sell 80 quarter loaves or a like proportion of other sizes, which it was reckoned each quarter of flour ought to yield.

**Sale by Weight.**—The acts now regulating the manufacture and sale of bread in Great Britain are one of 1822 (Sale of Bread in the City of London and within 10m. of the Royal Exchange), and the Bread Act of 1836, as to sale of bread beyond 10m. of the Royal Exchange. The acts require that bread shall be sold by weight, and in no other manner, under a penalty not exceeding 40 shillings. This does not, however, mean that a seller is bound to sell at any particular weight; the words quarter and half-quarter, though commonly used and taken to indicate a 4lb. and 2lb. loaf respectively, have no legal sanction. That is to say, a baker is not bound to sell a loaf weighing either 4lb. or 2lb.; all he has to do, when a customer asks for a loaf, is to put one on the scale, weigh it, and declare the weight. When bread is sold over the counter it is usual for the vendor to cut off and tender a piece of bread to make up any deficiency in the loaf. This is known as the "overweight."

There is little doubt the somewhat misty wording of the Bread Acts lends itself from time to time to a good deal of fraudulent dealing.

When bread is sold over the counter, two loaves may be 6oz. short, while the piece of makeweight may not reach an ounce. The provision as to selling by weight does not apply to fancy bread and rolls. No exact definition of "fancy bread" has ever been laid down, and it must be largely a question of fact in each particular case. All bakers or sellers of bread must use avoirdupois weight, and must provide, in a conspicuous place in the shop, beams, scales and weights, in order that all bread there sold may from time to time be weighed in the presence of the purchaser. The penalty for using any other weight than avoirdupois is a sum not exceeding £5 nor less than 40 shillings, and for failing to provide beams and scales a sum not exceeding £5. The acts also define precisely what ingredients may be employed in the manufacture of bread, and impose a penalty not exceeding £10 nor less than £5 for the adulteration of bread. (See further under ADULTERATION.)

Although the Act of 1836 extends to the whole of Great Britain (Ireland excepted) out of the city of London and beyond 10m. of the Royal Exchange, yet in many Scottish burghs this act is replaced by local acts on the sale of bread. These are in all cases of a much more stringent nature, requiring all batch or household bread to be stamped with the reputed weight. Any deficiency within a certain time from the withdrawal of the bread from the oven is an offence.

It may be noted that the Acts of 1822 and 1836 define precisely what may and may not be sold as bread. It is laid down in section 2 that "it shall and may be lawful . . . to make and sell . . . bread made of flour or meal of wheat, barley, rye, oats, buckwheat, Indian corn, peas, beans, rice or potatoes, or any of them, and with any (common) salt, pure water, eggs, milk, barm, leaven, potato or other yeast, and mixed in such proportions as they shall think fit, and with no other ingredients or matter whatsoever."

**Sanitation of Bakehouses.**—The sanitary arrangements of bakehouses in England were first specially regulated by the Bakehouse Regulation Act, 1863, which was repealed and replaced by the Factory and Workshop Act, 1878; this act, with various amending acts, was in turn repealed and replaced by the Factory and Workshop Act, 1901. By the Act of 1901 a bakehouse is defined as a place in which are baked bread, biscuits, or confectionery from the baking or selling of which a profit is derived. The duty of enforcing the Act of 1863 was placed on the local authorities; since then there have been sundry vicissitudes in the respective jurisdictions of the factory inspectors and of the local authorities in the matter of sanitary supervision of bakehouses, but the position now reached is that the local authority administer the general sanitary provisions in the Factory Acts so far as regards bakehouses which are "workshops" (i.e., where no mechanical power is used in aid of the manufacturing process) and also, as regards all bakehouses, certain special provisions which apply to bakehouses only.

The more important of these are: (1) No water-closet, etc., must be within or communicate directly with the bakehouse; every cistern for supplying water to the bakehouse must be separate and distinct from any cistern supplying a water-closet; no drain or pipe for carrying off sewage matter shall have an opening within the bakehouse. (2) The interior of all bakehouses must be limewashed, painted or varnished at stated periods. (3) No place on the same level with a bakehouse and forming part of the same building may be used as a sleeping place, unless it is effectually separated from the bakehouse and has an external window. (4) No underground bakehouse (one of which the floor is more than 3ft. below the surface of the footway of the adjoining street) shall be used as a bakehouse unless it was so used in 1901 and then only if certified by the district council as suitable for the purpose.

Mention may also be made of a welfare order made by the secretary of state in 1927 and enforceable by the factory inspectors, which requires (*inter alia*) suitable washing facilities and drinking water to be provided.

(G. F. Z.)

**BREAD: HOME MADE**

The making of home made bread demands ingredients of flour, fat, liquid and the correct amount of sugar, salt, yeast, the maintenance of an even temperature during the rising process, skillful kneading and proper baking. Different kinds of wheat flour vary in bread-making value according to the gluten that can be developed in them. Gluten makes the bread dough elastic so that it can expand and holds the bubbles of gas formed by the yeast. Yeast, which serves as the leavening agent, may be used in the commercially prepared dry or compressed form or as it is made in the home in the liquid form. Liquids used in bread making are milk, water and potato water. Any animal or vegetable fat may be used in making bread and its purpose is to increase the fuel value of the bread.

**Oven Conditions.**—If using a coal range make a good fire and bank it against the side of the oven. If more coal is needed place it at the opposite side of the grate. Let the heat lessen later. When cooking by gas or electricity heat the oven 15 to 20 min. before the loaves are put in. Lessen the heat after the loaves have risen well and are slightly brown. If the oven is too hot the crust will become dark and hard and the inside heavy; if too cool the bread will be pale and dry from too slow cooking. If bread is sodden the dough may have been too moist or the loaves, whilst hot, put to cool so that the steam could not escape; if the bread rises too much and is full of holes the oven was too cool or the dough rose too fast because it was left in too hot a place. If the yeast is mixed either too hot or too cold the bread will not rise well as the yeast plant is killed by too great heat or by extreme cold. An oven temperature of 350° F is needed at first. Test with an oven thermometer or sprinkle a little flour on the oven sheet; if it turns dark brown in 4–5 min. the oven is ready.

These directions are for baking bread in the oven of a domestic coal range, gas or electric cooker. It is not advisable to bake large loaves in small ovens. If a quartern— $3\frac{1}{2}$  lb. of flour—is used make it into two loaves. If the oven is very small only rolls or 1 lb. or  $\frac{1}{2}$  lb. loaves should be attempted. Brown bread should always be made into small loaves. It takes a little longer to cook than white.

**White Bread.**—7 lb. flour, 1 tablespoonful salt, about 2 qt. of warm water, 2 oz. compressed yeast. Sieve the flour and salt into a warm bowl. Make a hollow in the middle. Crumble the yeast into a warm basin, cream it with a wooden spoon and gradually stir in a pint of warm water. Pour this into the hollow in the flour and gradually stir in enough flour to form a thick smooth batter. Sprinkle the surface with a little more flour, cover the basin with a thick cloth and leave in a warm place until the sponge has risen and is covered with bubbles—15 to 20 minutes. Mix in the rest of the flour and lukewarm water gradually until a soft dough is formed. All the water may not be required. Turn on to a floured board, flour the hands and knead thoroughly until the dough ceases to cling to the hands, about 15 minutes. Flour the basin, replace the dough, cut a "X" on the top, cover with a cloth and leave in a warm place out of a draught for about one hour or until the dough is twice its original size and the surface covered with little cracks. Turn on to the board, knead again lightly, shape into loaves, put into greased and floured tins which must only be half filled, or make into cottage loaves, and place on greased and floured baking sheets. Cover and leave in a warm place to rise until the dough has risen to the top of the tins, or until cottage loaves are nearly double their size. Bake 2 lb. loaves from 1 to  $1\frac{1}{4}$  hours, 4 lb. loaves from  $1\frac{1}{2}$  to 2 hours. When cooked, the bread shrinks from the pan and sounds hollow if tapped on the bottom. Cool on a sieve and do not put away until cold.

**Brown Bread.**—14 oz. brown meal, 14 oz. household flour,  $\frac{1}{2}$  oz. compressed yeast, 2 gills water, 1 gill milk, 2 level teaspoonfuls salt, 1 oz. butter, 1 teaspoonful castor sugar. Sieve the flour and salt, add the meal, and rub in the butter. Beat the yeast and sugar to a cream, make the milk and water tepid, stir them to the yeast and strain into the centre of the flour. Mix a little flour into the liquid, cover with a cloth and put in a warm place for 20 min. or until covered with air bubbles.

Work in the rest of the flour, adding more warm milk or water, if necessary, to make a soft dough. Knead lightly but thoroughly. Shape into 2 small loaves and half fill the greased and floured tins. Cover. Set in a warm place until the bread rises to the tops of the tins, about 1 hour. Bake at once for about 1 to  $1\frac{1}{4}$  hours. The oven should be hot for 15 min., then decrease the heat. The butter may be omitted and water alone used for mixing.

(D. C. PE.)

**BREADALBANE, JOHN CAMPBELL**, 1ST EARL OF (c. 1635–1717), son of Sir John Campbell of Glenorchy, Bart., and of the Lady Mary Graham, daughter of William, earl of Airth and Menteith, was born about 1635. He took part in the abortive royalist rising under Glencairn in 1654, and was one of those who urged Monk to declare a free parliament in England to facilitate the Restoration. He sat in the Scottish parliament as member for Argyllshire from 1669 to 1674. As principal creditor he obtained in Oct. 1672, from George, 6th earl of Caithness, a conveyance of his dignities, lands and heritable jurisdictions; and after the latter's death he was created on June 28 1677, earl of Caithness and viscount of Breadalbane. In 1678 he married the widowed countess of Caithness. In 1680 he invaded Caithness with a band of 700 men and dispossessed the earl's heir male. The latter, however, was subsequently confirmed in his lands and titles, and Campbell on Aug. 13 1681, obtained a new patent creating him earl of Breadalbane and Holland, viscount of Tay and Paintland, Lord Glenorchy, Benederaloch, Ormelie and Weick in the peerage of Scotland, with special power to nominate his successor from among the sons of his first wife. In 1685 he was a member of the Scottish privy council. Breadalbane was the most powerful man in Scotland after Argyll, and it was of high moment to King William to gain him and obtain his service in conciliating the Highlanders. Breadalbane at first carried on communications with Dundee and was implicated in the royalist intrigue called the "Montgomery plot," but after the battle of Killiecrankie in July 1689 he made overtures to the Government, took the oath of allegiance, and was entrusted with a large sum of money by the Government to secure the submission of the clans. On June 30 1691, he met the Jacobite chiefs and concluded with them secret articles by which they undertook to refrain from acts of hostility till October, gaining their consent by threats and promises rather than by the distribution of the money entrusted to him, which, it was believed, he retained himself.

On Aug. 27 a proclamation was issued offering indemnity to all those who should take the oath of allegiance before Jan. 1 1692, and threatening all those who should refuse with a military execution and the penalties of treason. All the chiefs took the oath except MacIan, the chief of the MacDonalds of Glencoe, who postponed his submission till Dec. 31, and was then prevented from taking the oath till Jan. 6 1692, through the absence of a magistrate at Fort William. This irregularity gave Breadalbane an immediate opportunity of destroying the clan which had for generations lived by plundering his lands and those of his neighbours. Accordingly, together with Argyll and Sir John Dalrymple (afterwards Lord Stair), Breadalbane organized the "Massacre of Glencoe," when the unfortunate MacDonalds, at the moment when they were lavishing hospitality upon their murderers, were butchered in cold blood on Feb. 13 1692. Breadalbane's astuteness, however, prevented the disclosure of any evidence against him in the enquiry afterwards instituted in 1695. He was imprisoned in Edinburgh Castle in September on the ground of earlier negotiations with the Jacobite chiefs, but he was released when it was known that he had been acting with William's knowledge.

Breadalbane did not vote for the Union in 1707, but was chosen a representative peer in the parliament of Great Britain of 1713–15. His co-operation with the English Government in securing the temporary submission of the Highlands was inspired by no real loyalty, and he encouraged the attempted French descent in 1708, refusing, however, to commit himself on paper. At the Jacobite rising in 1715 he excused himself on Sept. 19 from obeying the summons to Edinburgh on the ground of his age and infirmities; but nevertheless the next day visited Mar's camp at Logierait and afterwards the camp at Perth. He had taken money

for the whole 1,200 men he had promised and only sent 300. His 300 men were withdrawn after the battle of Sheriffmuir, and his death, on March 19 1717, rendered unnecessary any enquiry into his conduct.

**BREADALBANE** district, Perthshire, Scotland, bordered on the north by Atholl, east by Strathay, south by Strathearn and west by the districts of Argyll and Lorne, and occupying some 1,020sq.miles. Ben Lawers (3,984ft.), Ben More (3,843ft.), and Ben Lui (3,708ft.) are the principal peaks. Loch Tay is the chief lake, and the rivers are the Orchy, Dochart, Lochay, Lyon, Almond and the upper Tay. The population mostly centres in Aberfeldy, Fortingal, Kenmore and Killin. It is a land of deer forests, shooting and fishing; only a little soil in glens and straths is cultivable. The district has given the titles of earl and marquess to the Campbells of Glenorchy.

**BREAD-FRUIT.** This important staple food of the tropical islands in the Pacific ocean is the fruit of *Artocarpus incisa* (family Moraceae). The tree attains a moderate height, has large, acutely lobed, glossy leaves, the male flowers in spikes, and the female flowers in a dense head, which by consolidation of the fleshy carpels and receptacles form the fruit. This is globular, about the size of a melon, with a tuberculated or nearly smooth surface. Many varieties are cultivated; in the best kinds the seeds are aborted. The tree is a native of Polynesia and Malaysia, where its fruit occupies the position held by cereals in temperate latitudes. Distinct varieties ripen at different periods, affording a nearly constant supply; it is gathered just before it ripens, when it is gorged with starchy matter. It may be prepared in a variety of ways, the common practice in the South Sea Islands being to bake it entire in hot embers and scoop out the interior, which

BY COURTESY OF THE DIRECTOR OF THE ROYAL BOTANIC GARDENS

**BREAD-FRUIT, A TREE OF EXTENSIVE USEFULNESS IN THE SOUTH SEA ISLANDS, FIRST CAME TO ENGLISH ATTENTION IN 1688. ITS FRUIT SUPPLIES FOOD AND ITS BARK, FIBRE FOR CLOTH**

A. Branch, about one-twelfth size, with male flowers in a club-shaped and female flowers in a rounded cluster, which, being deciduous, fall at maturity. B. Cross section of a male cluster with numerous flowers. C. Single male flower with outside envelope in two parts and single fertilizing cell. D. Single female flower with reproductive cell, style, and two-lobed receptive spot which receives and develops the pollen grain. E. Reproductive cell. F. Section of fruit

should have a soft smooth consistence, fibrous only towards the heart, with a taste comparable to that of boiled potatoes and sweet milk. Of this fruit A. R. Wallace (*Malay Archipelago*) says: "With meat and gravy it is a vegetable superior to anything I know either in temperate or tropical countries. With sugar, milk, butter, or treacle it is a delicious pudding, having a very slight and delicate but characteristic flavour, which, like that of

good bread and potatoes, one never gets tired of." A common method of preserving the fruit consists in cutting it into thin slices, which are dried in the sun. From such slices a flour is prepared which is used for puddings, bread, and biscuits, or the slices are baked and eaten without grinding. The tree also yields cloth from the fibrous inner bark; the wood is used for canoes and furniture; and a glue and caulking material are obtained from the viscid milky juice which exudes from incisions in the stem.

The bread-fruit is found throughout the tropical regions of both hemispheres, and its introduction into the West Indies is connected with the famous mutiny of the "Bounty."

A similar but inferior fruit is produced by an allied species, the jack, *A. integrifolia*, growing in India, Ceylon and the Eastern Archipelago. The large fruit is 12-18in. long by 6-8in. in diameter, and is much eaten by the natives in India. This tree is valuable on account of its timber, which has a grain similar to mahogany.

**BREAD MANUFACTURE.** In bread making, as in other industries, the aim of modern development is to make the process wholly automatic. Nothing is more desirable than that this ideal should be attained, for where handling of the material can be dispensed with it is certain that economy in production must be the result, whilst from a hygienic point of view the benefits are obvious. An authority states that "the doughing machine without doubt gives the greatest ease to the workman, the greatest peace of mind to the owner, and the greatest satisfaction to the consumer," and there is no doubt that even in smaller bakeries economy may be effected by even a partial substitution of hand labour by machines, of which the range is sufficient to meet all needs. The process of bread making may conveniently be divided into four sections—namely, flour handling, dough making, loaf making and baking; and although detailed attention must be directed to the completely automatic plant, for the most part the machines involved are none the less applicable to bakeries which are only in part automatic.

**Flour Handling.**—Handling of the flour entails blending, sifting and weighing. The machines used for blending are either continuous in action or work on the batch principle. In the former the hopper of the machine is divided by partitions and the various flours fed into the compartments, at the bottom of which are adjustable feed rollers which can be controlled to deliver the requisite quantity of flour. It is claimed that such blending machines are efficient but it is doubtful whether any blend can be perfect and regular unless made in a batch machine. This type is similar in action to that of the universal kneader and each batch of flours is thoroughly mixed in it before being allowed to pass out to the elevator, which carries the flour from the blender up to large hoppers where the different mixtures are stored. A sifting machine is fitted below the storage hopper which serves the purposes of removing fluff or refuse, breaking up any lumps and thoroughly aerating the flour. The spiral brush sifter is an ideal machine for the purpose. The flour is fed into a chamber in which a spiral brush works against a semicircular sieve. This machine is rapid in action, easily cleaned and noiseless. The sifter delivers the flour into an automatic weigher. This machine is adjusted like the ordinary platform weigher, and as it discharges it automatically cuts off the supply of flour from the sifter. In large plants, where there are two or more storage hoppers, travelling mechanism allows the weigher to be moved to a position underneath any one hopper. An arrangement suitable for smaller bakeries comprises a blending machine, sifter and fixed weigher to serve one kneading machine. From the weigher the flour discharges direct into the kneading machine and is ready to be made into dough.

**Dough Making.**—Pure water at the right temperature for dough making is secured by using a tempering tank. Such tanks, of which the inside is either tinned, galvanized or of copper, are fitted with hot and cold water supplies, any temperature being thus easily obtained. A thermometer and gauge glass enable the temperature and quantity of the water within the tank to be seen at a glance. In bakeries where the process includes the making of a sponge, a sponge mixer is used. This consists of a dough mixer in which the materials are stirred together by means of horizontal blades carried on a revolving vertical spindle, the latter being

## BAKING AND COOLING THE LOAVES

The bread oven and cooler in Lyons' bakeries, Cadby hall, London. The bread is being taken from the oven and transferred to the cooler, where it remains for two hours before being conveyed to the automatic wrapping-machine. This oven is capable of baking 2,800 loaves per hour

# BREAD MANUFACTURE

BY COURTESY OF (1, 4) J. LYONS AND COMPANY, LTD., (2, 3) THE NATIONAL BISCUIT COMPANY

## SEVERAL PROCESSES OF BREAD AND BISCUIT MAKING

1. Rolls being discharged automatically from the oven in the "Vienna" bakery of Lyons & Co.
2. A row of gas ovens used for baking sugar wafers
3. One of the mixing rooms of the National Biscuit company
4. Dough being brought from the dividing-machine in rounded places ready for the tins

raised clear of the mixer when mixing is finished, and the sponges are then allowed to rise in troughs. The kneading machine has long been the most familiar mechanical unit in the bakehouse and dates at least to 1760 when a Frenchman, Salignac, devised a model in which harrow-shaped arms, mechanically operated, mix the dough in a trough. The Boland machine, which dates from about the middle of the 18th century, was also of French origin and was probably the first which efficiently replaced the work of human arms. It consisted essentially of a trough in which revolved a pair of blades operating in the manner of alternate screws. This machine was adopted widely in other countries than France and was one of the first to be used in the British isles. Amongst the modern kneading machines which are suitable for making various types of dough is that known as the Universal. The body of the machine is a metal trough in which two blades of special shape revolve side by side on horizontal axes. The base of the trough is so shaped as to follow the path of the two arms so that no particle of dough can escape thorough kneading. The machine can be tilted easily either by hand or by power, without stopping the arms, so that the discharging of the finished dough into the dough truck is simply accomplished. The "Viennara" dough kneader is also widely used. In this the dough is made in a round pan standing on a platform which revolves about a vertical axis. The kneading is effected by an arm, T-shaped at the end, which reaches over and into the pan. The end of the arm sinks into the dough, travels across the pan and then rises again. As the pan is itself revolving, fresh dough is repeatedly brought within reach of the arm. In this way the dough is very gently and continuously stretched and folded. When the kneading is finished the pan is wheeled away for proving, a dough truck in this case being unnecessary, and afterwards returned to the machine for "cutting back." In a second type of this machine the revolving pan is not movable, but has a hinged door through which the dough can readily be discharged when kneading is complete.

**Loaf Making.**—The loaf making process is begun by division of the dough into pieces of suitable and uniform size. Until the year 1896 this was invariably done by hand, but at that time the first automatic dough divider was put on the market and this machine marked a very substantial advance in the mechanical equipment of bakeries. The success of these machines depends largely upon the amount of punishment which the dough receives during the operation of dividing, for, if it is treated too severely, the after effects are serious and will be reflected in the finished loaf. The division is effected by pressing the dough into cylinders, of which there may be one, two, or three, in accordance with the output of the machine, and which are adjustable in size so that the correct weight of dough may be included each time they are filled. In the United States, the number of cylinders is usually rated 2, 4 and 6. The contents of the cylinders are automatically ejected and the pieces of dough fall on to a travelling band and are carried forward. Great importance attaches to the actual method by which the cylinders are filled and this varies in different models. In a widely used type the dough is fed into the hopper and by means of a weighted ram the necessary force is applied to press it into the cylinders. The pressure is adjustable to suit different types of dough and it is said that the punishment inflicted upon the latter by this method is reduced to a minimum. "Handing up," "balling up" or "rounding" in order to restore uniformity to the pieces of dough after treatment in the divider necessarily follows. This was formerly performed by hand, a very unhygienic operation, but is now carried out successfully by machines of which the "conical" and "flexible" types are well known. The former consists of a revolving cone-shaped table with grooved surface for gripping the dough, around which is a stationary spirally-shaped trough supported from above. The pieces of dough are fed into the trough at the base of the cone and the latter in revolving works them up to the top, to be discharged on to a travelling band. As the piece of dough ascends it is forced against the side of the trough and undergoes a screw-like motion which makes it uniform throughout and ensures stretching of the skin in every direction. At the delivery end of the trough the slope is decreased, with the result that the "tail" of the piece of dough is

"tucked in" and it rolls off the table practically spherical. The principle underlying the action of the "flexible" moulder is identical with that of the "conical" machine, except that the conical surface is replaced by an inclined moving table composed of metal laths carried on chains and so forming an endless belt. The moulding troughs, which in this case may be two or more in number, are straight and are adjustable in size to suit different weights of dough and varying degrees of working. Handling of the dough after it leaves the handing-up machine has been made unnecessary by the advent of the automatic swinging tray prover. The pieces of dough coming from the handing-up fall on to trays and travel into the proving chamber, which is warmed to the required temperature and supplied with moist vapour to prevent a skin from forming on the loaves. The trays, carried on chains, move through the prover by a circuitous route devised to save floor space and the speed is adjustable to give the correct time of proving. The damp heat within the prover necessitates regular and thorough cleaning and the suspended trays are easily removable for this purpose. The loaves on coming out of the prover are tipped on to a travelling band ready for the final moulding machines. These are similar in operation to the handing-up or preliminary moulding machines, but are fitted with a splitting device for cutting the loaf in two when making cottage bread and with a shaping device for use with "tin" bread. A final prover completes the loaf-making process and the loaves are then ready for the oven.

**Bread Baking.**—In early times the oven, which was a flat baking space built in brickwork, was heated internally by wood or coke. Externally heated ovens followed, in which the baking chamber was surrounded by flues leading from furnaces fired with coke or coal. A marked step forward was, however, taken when about the middle of the 19th century the Perkins steam pipe oven was introduced. Rows of sealed iron pipes containing water are placed at the crown and sole of the oven. The pipes project outside the oven and the projecting ends are heated. The steam produced in the pipes is much superheated and the temperature of the oven is by this means readily raised to 450–500° F. This mode of heating produces a steady but not a flash heat, and the oven can be used continuously with the minimum of attention. The old method of charging the oven with the hand peel has been superseded in modern machine bakeries by the draw plate, or the Peel or travelling oven in the United States. The draw plate is mounted on wheels and is drawn out of the oven, charged with loaves and then returned. Decker ovens in which one baking chamber is built over another are used in some cases. It may be said that the problem of the completely automatic plant for baking "tin" bread has been solved by the production of the swinging tray travelling oven with which is combined a swinging tray automatic final prover. The loaves leave the final moulder and are deposited on the trays which pass continuously through prover and oven. The empty baking tins move back on the trays over the top of the oven to the feed end of the prover, when they are charged afresh. The bread is not handled even on leaving the oven for it passes next to a swinging tray cooler and is then automatically wrapped in paper for delivery. A notable development in oven construction is the travelling plate oven heated directly by gas. This oven can be included in the wholly automatic bread-making plant and can be used for baking all types of bread. (R. T. C.)

#### IN THE UNITED STATES

Commercial baking in the United States is a large and growing industry. It ranks second among the food and high among the manufacturing industries. In 1927, 18,129 baking establishments employing 171,995 wage earners used \$693,236,163 worth of materials and manufactured goods worth \$1,394,700,224. Of the total production 50.3% was in the form of bread and rolls, 17.6% biscuits, crackers and buns, 16.4% cakes, 4.4% pie and other pastries and 11.3% other products. In addition to using 38,782,580 bbl. of wheat flour and 2,103,509 bbl. of rye and other flours, the baking industry used 789,238,721 lb. of sugar, 450,689,325 lb. of butter, lard and other shortenings, milk and eggs valued at \$53,546,320 and millions of dollars worth of yeast, malt, syrups, salt and other essential bread ingredients.

During the period 1921-28 many wholesale bakeries were consolidated and large organizations now operate chains of plants, in some cases covering the entire country. This joining of effort and production has not reduced the field covered by the retail baker, nor will bread monopolies ever be possible, for the baking of bread and cake is essentially a local industry. In the manufacture of biscuits and crackers, however, which are sold in package form under conditions which protect the products from deterioration, large-scale production and distribution over wide areas is possible. The consolidation of bread and cake plants is limited to operating control and the products are still sold within a restricted area. The quality of baked products is steadily improving. This is due both to the use of better materials and formulae and to the development of sanitary methods of production and handling. The use of enriching materials such as whole and skimmed milk has improved the character of bread and its nutritive value. The idea that bread from white flour is innutritious is now recognized as erroneous.

**Arrangement of Plant.**—Improved bread and cake quality is secured through the improved processes and machinery used in the modern bakery. In the development of the industry the bakery has grown from a single floor to a building several stories high. The flour purchased in car-load quantities is stored on the upper floor where it is matured or aged for several months before it is delivered to the mixing and sieving machines where it is blended *en route* to the automatic weighing devices on the mixing-room floor below. Water of definite temperature is added to the weighed flour in the mixer together with weighed amounts of yeast, sugar, salt and in most cases condensed or dried milk. The dough made from these materials is placed in large troughs each holding 1,000 lb. of dough and sent to the dough or fermentation rooms where it undergoes a process of rising or fermenting for several hours. During the development of the yeast the dough is punched or kneaded several times to release the gas generated by the growing yeast plant and to develop the gluten of the flour under ideal conditions. The dough is then taken from the troughs and passes through automatic dividers which cut out pieces of uniform size for making 1 lb. and 1½ lb. loaves. The pieces of cut dough are passed on to a machine called the "rounder-up" which produces shape and form. The ball-up dough then slowly passes through a proofing chamber which is kept at a uniform temperature and in which the dough lying in slowly moving trays again expands under the influence of the growing yeast. From this point it passes to moulding machines which roll and shape it to forms to fit the bread pans in which it enters the oven for baking.

**Motive Power.**—The modern bakery is electrically equipped. Every operation which can be performed by machinery is mechanical and the power is usually supplied by electric motors which are a part of each machine. In the development of electrically driven mixers, special devices have been installed which not only make every operation mechanical but also remove the possibility of injury to the workmen.

**Ovens.**—The modern bakery demands a type of oven in which the heat can be quickly and uniformly applied and into which the dough can be loaded and the baked bread removed with no loss of time. This need has resulted in the building of travelling ovens in which the hearth moves forward from the loading end to the exit where the baked loaves are delivered in a never-ceasing stream. Other types of travelling ovens convey the pans containing the dough through a uniformly heated chamber, delivering them finally at the initial point where the same workman who loads the travelling trays removes the baked bread.

**Fuel.**—Coal, coke, gas, oil and electricity are used in firing modern bake-ovens, the type used being determined chiefly by the cost per unit quantity of bread baked. Where electricity is cheap it is the ideal fuel. Travelling ovens are usually gas-fired under systems which give an automatic control over the gas burned and heat obtained. The earlier types of ovens in which wood, coal and coke are used as fuel are rapidly giving way under the development of processes of heating which are automatic, dustless and cheap.

**Wrapping and Delivery.**—Sanitary legislation and development of more hygienic practices in handling food supplies have compelled the wrapping of bakery products so that they are fully protected against dust, dirt and contamination by handling. As the baked loaves leave the oven they pass to a conveyor which delivers them to travelling racks on which they are cooled to room temperature. When thoroughly cool the loaves pass to automatic wrapping machines which envelop them in parchment or paraffin paper and seal them in an air-tight package. They then go to the shipping-room where they are packed in wood or metal baskets or in more modern practice in large cardboard cartons for shipment to distant points by truck or express. The products intended for local delivery are placed in specially built delivery wagons; the usual practice of distributing bread from the wholesale bakeries is through the retail grocer who purchases bread daily from a number of companies and in turn delivers it still in its original wrapper to the housewife.

**Modern Operation.**—Every operation in the modern bakery is automatically controlled and mechanically registered. The number of revolutions of the mixer is predetermined; the temperature of the water which makes the dough is thermostatically controlled; the heating of the dough in the process of mixing is held down by chilled air or brine-cooled mixer walls; the temperature and humidity of the dough room is fixed, the speed of the divider, rounder, proofer, moulder, travelling oven, cooler and wrapping machine is so synchronized that lost motion or wasted time in any operation is impossible. Indeed, in a decade baking has become fully mechanized. The craft worker is unnecessary. Mechanics to run the machines, chemists to buy the ingredients and prepare the formulae, technicians to apply them to actual shop practice, have taken the place of the craftsman baker who less than a generation ago was indispensable to the making of bread.

(H. E. BA.)

**BREAD TICKET.** In the World War, the scarcity of cereals in Europe forced nearly all the belligerent powers, and some of the neutrals, to ration bread. This led to the issue of bread-tickets or coupons as the obvious means of distributing supplies equitably. In Germany and Austria, the consumers were supplied with bread-tickets as early as 1915; the cards bore detachable coupons, numbered and dated to prevent fraud. Later, France and Italy followed suit, and Scandinavia, Holland and Switzerland found it necessary to issue bread-tickets. In the United Kingdom, rationing was adopted only after much argument and delay. Finally, ration books for some foods were issued; and each consumer had to choose and register with a particular retailer, but although the rationing of bread was contemplated it was not put into practice. (See RATIONING.)

**BREAKING BULK,** a nautical term for the taking out of a portion of the cargo of a ship, or the beginning to unload; and used in a legal sense for taking anything out of a package or parcel, or in any way destroying its entirety. In England it was important in connection with the subject of bailment, involving the curious distinction that where a bailee received possession of goods in a box or package, and then sold them as a whole he was guilty only of a breach of trust, but if he "broke bulk" or caused a separation of the goods, and sold a part or all, he was guilty of felony. This distinction was abolished by the Larceny act (1861), which enacted that whoever, being a bailee of any chattel, money or valuable security, should fraudulently take or convert the same to his own use, or the use of any person other than the owner, although he should not "break bulk" or otherwise determine the bailment, should be guilty of larceny (§ 3).

**BREAKWATER,** a barrier intended to break the force of water at a particular place. A breakwater provides the artificial protection necessary, when a harbour is formed in an exposed situation, to supplement or complete such natural shelter as may be afforded by the configuration of the coast line or by the presence of outlying islands, reefs, etc. (see also the article HARBOURS). Although a harbour pier or jetty may be so placed and built as to serve the double purpose of a berthing place and a breakwater, the term breakwater is generally confined to a struc-

BY COURTESY OF THE CIVIL-ENGINEER-IN-CHIEF, ADMIRALTY

FIG. 1.—CROSS SECTION (1927) OF THE PLYMOUTH BREAKWATER. IT IS SUBSTANTIALLY THE SAME AS THE SECTION COMPLETED BY JOHN RENNIE IN 1829

ture used solely for protection; indeed, in some cases breakwaters are isolated, so as to be cut off by water from the shore, as at Plymouth.

Breakwaters must be made sufficiently strong to withstand the impact of the waves during the worst storms to which they are exposed. It is therefore essential, before constructing a breakwater, to investigate carefully the exposure of the site, the distance of any sheltering land in the most stormy direction, the slope of the beach and the depth of the sea in the neighbourhood of the shore, and the protection, if any, afforded by outlying shoals or sandbanks. In a tidal sea, the height required for a breakwater and the extent of it exposed to breaking waves is affected by the difference in level between high and low water. The nature and the extent of any drift of sand or shingle along the shore must be ascertained. A study of the conditions of the currents is also necessary in order to avoid, in planning the works, the placing of the entrance to the sheltered area in such a position as to expose ships making the harbour to inconveniently strong cross-currents. These and other similar problems face the engineer in planning the form and situation of the protective works of a harbour.

**Winds.**—Observations of the force, prevalence and direction of the winds belong to the science of meteorology (*q.v.*), but such records are valuable to the engineer in indicating from which directions, open to the sea, the worst storms, and consequently the

maximum distance in a certain direction from the nearest land—or, as it is termed, the “fetch”—coincides with the line travelled by the strongest gales. The dimensions, indeed, of waves in the worst storms depend primarily on the extent of the sea in which they are raised; though in certain seas they are occasionally greatly increased by the exceptional velocities attained by hurricanes and typhoons.

Waves have been found to attain a maximum height (measured from trough to crest) of about 20ft. in the Mediterranean, 25ft. in the Bay of Biscay and 40ft. in the Atlantic ocean; whilst waves of 50 to 60ft. in height are said to have been observed in the south Atlantic ocean off the Cape of Good Hope, where the expanse of sea reaches a maximum. The length of large waves bears no definite relation to their height, and is apparently due, in the long waves often observed in exposed situations, to the combination of several shorter waves in their onward course. Thus waves of over 600ft. in length have been met with during severe gales in the Atlantic ocean; whilst waves from 600 to 1,000ft. long are regarded as of common occurrence in the Pacific ocean during storms.

The rate of transmission of the undulation also varies with the exposure; for the ordinary velocity of the apparent travel of waves in storms has been found to amount to about 22m. an hour in the Atlantic ocean, and to attain about 27m. an hour off Cape Horn. The large waves observed in mid-ocean do not,

FIG. 2.—CROSS SECTION OF THE OUTER ARM OF PORTLAND OLD BREAKWATER

greatest waves, may be expected. Moreover, it is necessary for constructing or repairing a breakwater to know the period of the year when the calmest weather may be safely anticipated. In the parts of the world subject to periodical winds such as the monsoons, the direction and force of the winds vary with remarkable regularity according to the seasons, and even such uncertain occurrences as hurricanes and cyclones generally visit the regions in their track at definite periods of the year, according to the locality.

**Waves.**—The size of waves depends on the force of the wind and the distance along which it blows continuously, in approximately the same direction, over a large expanse of ocean. The greatest waves are, accordingly, encountered where the maxi-

however, reach the coast, because their progress is checked and their height and length reduced by encountering the shelving sea-bottom on approaching the shore.

The actual waves which have to be arrested by breakwaters therefore depend on the exposure of the site, the existence of continuous deep water close up to the shore and the depth in which the breakwater is situated. On the other hand, the height and consequently the destructive force of waves are increased on running up a funnel-shaped bay by the increasing concentration of the waves in the narrowing width, just as the tidal range of a moderate tidal current is much augmented by its passage up the bay of Fundy, or the Bristol channel into the Severn estuary. This effect is intensified when the bay faces the direction of the strongest

winds. Thus at Wick, on the north-east coast of Scotland, a mass of masonry weighing 1,350 tons, placed at the head of the breakwater projecting halfway across the bay and facing the entrance, was moved by the waves during a violent storm. On the same coast, a portion of Peterhead breakwater, weighing 3,300 tons, was shifted 2 in. in 1898. It has been estimated that the wave stroke necessary to move this mass amounted to 2 tons per sq.ft.

FIG. 3.—CROSS SECTION OF THE WEST BREAKWATER AT COLON, PANAMA

on the average over the face of the displaced wall. At Bilbao in Spain, where the bay, like that of Wick, is funnel shaped, a monolithic mass of 1,700 tons weight at the breakwater end was carried 105 ft. into the harbour during a severe gale (Dec. 1894).

Where outlying sandbanks stretch in front of a coast, as for instance the sandbanks opposite Yarmouth sheltering Yarmouth roads, large waves cannot approach the land, for they break on the sandbanks outside. Waves indeed always break when, on running up a shoaling beach, they reach a depth approximately equal to their height; and the largest waves which can reach a shore protected by intervening sandbanks are those which are low enough to pass over the banks without breaking. Waves often break in depths of water greater than their own height, and any sudden change in the level of the sea bed over which a wave is travelling may bring about its disruption even in water of considerable depth.

The force of the wind, as transmitted by degrees to the sea, is manifested as a series of progressing undulations without any material displacement of the body of water. So long as the wind continues to act on waves which it has brought into existence it continues to increase their height and length. The waves thus accumulate the energy which they receive from the wind. When a wave reaches a lee shore its energy has either to be dissipated by the breaking of the wave or to be reflected.

On encountering a vertical, or approximately vertical, obstacle to its onward course, each wave, on reflection, deals a blow against the obstacle proportionate to its size and rate of transmission. When a wave reaches shoal water the undulation is transformed into a breaking wave rushing up the sloping shore, till, on its energy being spent, it recoils back into the sea.

A breaking wave concentrates its transmitted force on a portion of the water forming the undulation, which consequently strikes

FIG. 4.—THE CONCRETE BLOCK BREAKWATER AT CETTE, FRANCE

a more powerful blow over a limited area against any structure than the more distributed shock of a simple undulation beating against a vertical wall. Moreover, the recoil or backwash of broken waves produces a greater scour than the simple reflection of an undulation from a vertical wall. The materials forming the covering of the slope and the toe of a breakwater mound must therefore be able to resist this erosive effect. The large concrete blocks often placed pell-mell as protection on the sloping face of a rubble mound breakwater absorb much of the energy

of a breaking wave in their interstices and similarly reduce the force of the backwash. On the other hand, when a vertical surface is exposed to a heavy breaking wave a large mass of water is projected upwards and there is a heavy down stroke. Consequently the material at the toe of the wall is liable to displacement by the wash of recoil, unless the depth is sufficient to provide an ample cushion of water below the undulation. There are of course also stages of wave stroke to which a breakwater structure may be exposed which are intermediate between the complete breaker on a sloping beach and the pure reflection of a wave. (See also the articles WAVE THEORY and TIDES. Students of the subject should consult the works of Sir George Airy, Weber, Scott Russell, T. Stevenson, W. J. M. Rankine and W. H. Wheeler.)

**Protection of Unfinished Work.**—The protection of unfinished work during the seasonal periods of stormy weather is a difficult problem which has to be faced by the breakwater builder. Work may have to be entirely suspended for a portion of each year and the scar or unprotected end of the unfinished structure, exposed as it is on three sides out of four, is particularly liable to sea damage. At Bilbao, for instance, during the building of the main breakwater, long lengths at the outer end were destroyed year after year in the winter seasons. Special precautions are usually taken to secure the safety of unfinished work in such circumstances.

**Types of Breakwater.**—Breakwaters may be classified under four general types: (1) a simple mound of stone rubble or con-

FIG. 5.—CROSS SECTION OF WEST BREAKWATER EXTENSION AT PORT SAID

crete blocks, or a combination of the two materials; (2) a mound raised to near or above water level surmounted by a solid superstructure of masonry or concrete; (3) a mound foundation finished off at a considerable depth below water level and surmounted by an upright wall breakwater of concrete or masonry; and (4) an upright wall breakwater, built up solid from the sea bottom to the top. The second and third types (frequently referred to as composite breakwaters) are, in fact, combinations of the first and fourth types. The classification is in some degree an arbitrary one, and examples can be cited in which one type merges in another. Generally, the choice of type is determined by the materials available at the site, the depth of water, the nature of the sea bed and, in some cases, by the facilities and plant which are available for the execution of the work. The length of time allowable for the construction of a given length of breakwater has also, in some cases, a bearing on the choice of design and method of construction.

### (1) MOUND BREAKWATERS

A rubble mound consists of a mass of stone, just as it is obtained from a quarry, tipped into the sea along a predetermined line till the mound emerges out of the water. The stone is deposited from barges or is carried to the work in wagons run out from the shore on staging; frequently the two methods are combined. The larger masses of stone are often selected for placing in the more exposed parts of the work and on the faces of the breakwater, and for this purpose the use of cranes may be necessary. The mound thus deposited is gradually consolidated under the action of the sea and the weight of material, and a tolerably stable form is by degrees attained by continued deposits of stone. When the foundation is of soft and compressible material the stone rubble sinks into the sea bed owing to the weight of the superimposed materials. At Alexandria the rubble at the base of the

north breakwater extension (1905-8) sank to a level of 20ft. below the original bed, the silt of which was forced upwards at the sides of the mound.

The rubble mound system is wasteful of materials and entails a relatively high expenditure on maintenance. It can only be resorted to where quarries near at hand are able to furnish large supplies of stone at a cheap rate. When the site is an exposed one

FIG. 6.—OLD NORTH BREAKWATER AT ALEXANDRIA, WESTERN HARBOUR

storm waves carry the stones on the top, if unprotected, forward on to the harbour slope, while the recoil of the wave on the outer face draws down the stones on that side, thus flattening the slope. Frequent replenishing with a fresh deposit of stones is thus necessary. The inclination of the flattened sea slope, which extends from above high water to well below low water, depends on the exposure and the size of the stones on the face.

In order to avoid the injuries to which a rubble mound is subjected by waves various methods have been devised for protecting the top and the sea slope of the mound. For instance, the upper part of Plymouth, England, breakwater (fig. 1) has been covered over by granite and limestone paving set in cement. In other cases the surface stones are selected, roughly masoned and set close together as at Portland, England (fig. 2). The chief point of importance is to cover the outer slope and the top of the mound with the largest stones that can be procured, and when large stones are not readily obtainable concrete blocks furnish a convenient substitute.

**Concrete Block Protection.**—Where concrete blocks are employed it is usually as the outer covering on the top and sea slope of a rubble mound, as for example in the older breakwaters at Algiers, where the depth reaches 70ft., and at the ports of Cette and Bona (Algeria). The breakwater at Cette (fig. 4) has given trouble owing to the erosion of the sea bed and the unequal settlement of the coursed blocks. A more usual arrangement is to deposit the blocks at random or pell-mell. Other examples of blockwork protection are the north-east breakwater at Colombo

FIG. 7.—OLD INNER PORTION OF WEST BREAKWATER AT PORT SAID

harbour, the extension of the west breakwater at Port Said (1912-22) (fig. 5) and the older part of the north breakwater at Alexandria (1870-74). In this case concrete blocks compose the outer half of the mound, sheltering the inner half consisting of small rubble (fig. 6). Occasionally a mound breakwater has been formed entirely with concrete blocks, as for instance the main portion of the western breakwater at Port Said (1864-68) (fig. 7).

**Utility of Concrete Blocks.**—Concrete blocks possess the great advantage that they can be made wherever sand and shingle can be procured, and of a size only limited by the appliances which are available for handling them. In fact, in places where stone

of any kind is difficult to procure at a reasonable cost, as for instance at Port Said, concrete is indispensable. At Pará (Brazil) blocks made of Portland cement and sand (without any stone or shingle) were used in the construction of the port works. Large artificial blocks, moreover, by enabling a comparatively steep slope to be formed with them on the sea side of a mound breakwater, reduce considerably the amount of materials required; especially at exposed sites, and also for breakwaters extended into deep water. These large concrete blocks are deposited by cranes travelling on staging or on the completed portion of the work, or are tipped into the sea from a sloping platform on barges, or floated out between pontoons, or slung out from floating cranes or derricks. Sometimes when a mound breakwater has been raised out of water, advantage is taken of a calm period of the year and a low tide to form large blocks of concrete within timber framing on the top of the mound so as to afford additional protection.

#### Advantages and Disadvantages of Mound Breakwaters.

—The large mass of a mound breakwater gives it great stability; this type is, moreover, suited to construction on a sandy or silty sea bed. The large quantity of material required for its construction and the continuous maintenance necessary are, however, disadvantages. The type has, since the end of the 19th century, been employed to a limited extent, excepting perhaps in North America, and usually in comparatively sheltered positions of moderate depth. Well known examples of the mound breakwater, in addition to those already mentioned, are at Howth (the first example

BY PERMISSION OF H. MICHEL-SCHMIDT

FIG. 8.—CROSS SECTION OF THE DIGUE CARNOT AT BOULOGNE on a large scale in the British Isles) and Kingstown, both on Dublin bay, at Table bay (Cape Town) and in the outer part of the Nuovo mole at Genoa (1862-68). Instances of more recent construction are at Colon, Panama (fig. 3) and Takoradi, a Gold Coast harbour (1922-28), and the Courtney bay breakwater at St. John, New Brunswick (1912-20).

#### (2) MOUND BREAKWATERS WITH SOLID SUPER-STRUCTURE AT OR NEAR WATER LEVEL

This type is a modification of the first class and possesses most of its advantages and disadvantages. It comprises the majority of breakwaters constructed in the last quarter of the 19th and the early years of the 20th centuries; but with the growing necessity of providing artificial shelter in great depths of water it has become more usual to build breakwaters in such situations with superstructures carried down well below low water, as described later.

The solid superstructure reduces the amount of materials required, according to the depth at which it is founded, and the solid capping also serves to protect the top of the mound from the action of the waves. In the case of a mound breakwater, portions of the highest waves generally pass over the top of the mound, and their force is also to some extent expended in passing through the interstices between the blocks or stones; whereas a superstructure presents a solid face to the impact of the waves. A superstructure, accordingly, must be strongly built in proportion to the exposure and to the size of the waves liable to reach it. Special care, moreover, has to be taken to prevent the superstructure from being undermined, for the waves in storms, dashing up against this nearly vertical, solid obstacle, tend in their recoil down the face to scour and displace the materials of the mound at the outer toe of the superstructure and thereby undermine it. This risk is specially present where the superstructure is founded on the mound near low water level, and there is therefore no

## BREAKWATER

FIG. 9.—CROSS SECTION OF OUTER PORTION (1928) OF CASABLANCA BREAKWATER. DIAGRAM SHOWS THE TITAN CRANE USED IN BUILDING THE BREAKWATER. BY PERMISSION OF THE CHIEF ENGINEER, CASABLANCA

adequate cushion of water above the mound to withstand the recoil.

**Superstructures.**—The forms of superstructure exhibit considerable variations, ranging from a few concrete blocks laid in courses on the top of the mound, or a paving protected by a parapet wall on the sea side, up to a solid structure which is sometimes of considerable height in situations where there is a large tidal variation. The object aimed at in the case of superstructures founded at or near low water level is to lay the foundations on the mound at the lowest level consistent with building a solid structure with stones or concrete blocks set in mortar, out of water in the ordinary manner. The desideratum in the case of superstructure foundations laid at some depth below low water (*see* section [3])

These failures have led harbour engineers to recognize that destructive wave action can take place at depths of about 50 ft. in situations of great exposure to the ocean, and down to more than 30 ft. in the Mediterranean. In more sheltered positions the depths are proportionately less. Furthermore, the effect of the waves is at its maximum at sea level and the pressure of the wave on a vertical surface is more or less constant over the whole zone corresponding to the height of the wave, but below this zone it decreases rapidly (*see* E. Quellenec, Int. Congress of Navigation 1926, Paper 31). The pressure exerted at sea level by a wave in situations of great exposure may exceed three tons per square foot.

FIG. 10.—CROSS SECTION OF THE MARSEILLE BREAKWATER, SHOWING THE WAVE BREAKER OF LARGE CONCRETE BLOCKS ON THE RUBBLE MOUND

which follows) is to stop the raising of the mound at such a depth under water as to secure it from displacement by the waves. It is to the failure to provide adequately for this that the destruction or serious damage of many 19th century breakwaters is to be attributed. (*See* Sir W. Matthews, *Proc. Inst. C.E.*, vol. clxxi. [1908]. Sir Maurice Fitzmaurice has recorded, *Proc.* vol. ccxiv. [1922], that at Peterhead some 50-ton concrete blocks, joggled together and forming part of an apron protecting the rubble mound of breakwater about 45 ft. below low water, were displaced 50 ft. and overturned during a gale.)

Examples of rubble mound breakwaters surmounted by a superstructure founded at or near low water or sea level are those at Cherbourg, Holyhead and Marseille, the Galliera and Giano moles at Genoa, the San Vincenzo mole at Naples, the east harbour breakwater at Alexandria, the digue Carnot at Boulogne, the north breakwater at Algiers and those at Fishguard, Le Havre, Oran, Civitavecchia and Casablanca, the latter in a much exposed position on the Atlantic coast of Morocco (fig. 9). The very exposed breakwater at Alderney was commenced on this principle about the middle of the 19th century (*see* section [3] which follows).

FIG. 11.—THE CIVITAVECCHIA BREAKWATER. RUBBLE MOUND PROTECTED BY COURSED CONCRETE BLOCKS

The outer breakwaters at Leghorn and St. Jean de Luz have superstructures founded at low water level on concrete block mounds.

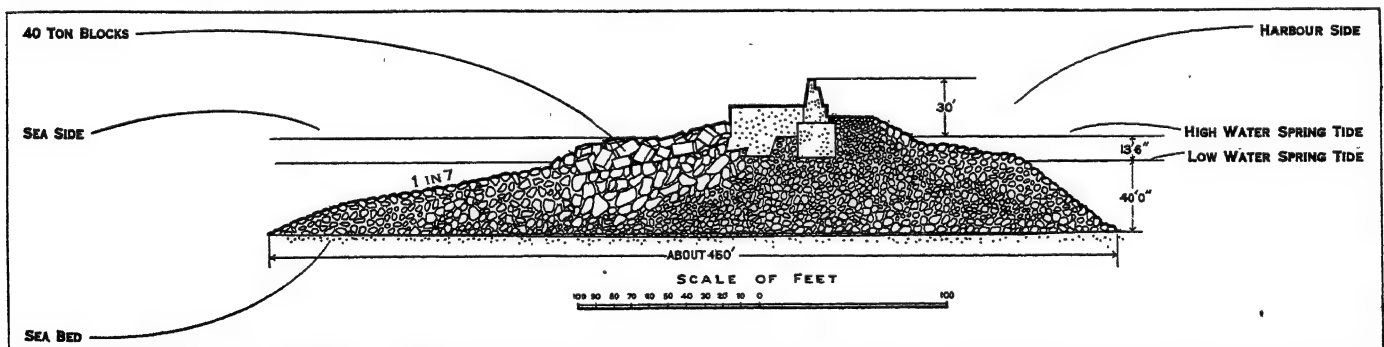

The breakwaters at Le Havre and Boulogne (fig. 8) are examples of the sorted mound surmounted by superstructure walls which, although founded well above low water, rise to a considerable height on account of the large tidal range at these ports, viz., 24½ft. and 29ft. respectively.

**Marseille Breakwater.**—The great breakwater at Marseille (see HARBOURS) is a successful example of the sorted rubble mound breakwater where a quay has been formed on the inner face, sheltered on the sea side by a narrow superstructure, founded at sea level, and protected on the sea slope of the mound from undermining by a wave breaker of large concrete blocks deposited pell-mell (fig. 10) on the rubble mound and having a flat slope from lowest water level up to the face of the superstructure wall well above highest sea level.

**Other Mediterranean Breakwaters.**—The outer portions of the San Vincenzo breakwater at Naples and the older parts of the Galliera mole at Genoa extend into depths of about 110ft. and 80ft. respectively, and have been provided with superstructures similar in type to, but more solid than, the superstructure at Marseille. The sorted rubble mounds are protected on the sea slope by stepped courses of concrete blocks from a depth of over

**Fishguard Breakwater.**—The breakwater at Fishguard, constructed between 1900 and 1918, is an interesting example of a composite breakwater which, in spite of weaknesses inherent in the original design, has been made suitable to the exposed situation in which it has been installed. It was at first designed as a rubble mound carried up to about high water with concrete superstructure and parapet; but the wastage of rubble on its sea face was found to be so serious that in 1913 it was decided to protect the rubble by the deposit of 40-ton concrete blocks placed pell-mell over the whole of the seaward face of the mound above low water springs (fig. 12). Previous to this, the quantity of stone rubble deposited annually for maintenance purposes on the sea face, of about half a mile in length, averaged 85,000 tons for several years.

**Danger of Non-solid Superstructures.**—Formerly, in constructing a large superstructure upon a rubble mound, it was a common practice to build an outer sea wall and an inner harbour wall, the intermediate space being filled, in the interest of economy, with rubble. A parapet wall was also generally erected on the sea side. This system of construction was adopted for the superstructures at Holyhead and Portland (inner arm), and at St. Catherine's, Jersey. Alderney, the Tyne and the Colombo south-west breakwaters were also commenced on this system (see section [3] which follows); but experience showed the danger in

BY COURTESY OF MESSRS. COODE, FITZMAURICE AND WILSON

FIG. 12.—CROSS SECTION OF FISHGUARD BREAKWATER. RUBBLE MOUND WITH SOLID SUPERSTRUCTURE PROTECTED BY 40-TON PELL-MELL CONCRETE BLOCKS

20ft. below sea level. The outer extension of the main breakwater at Civitavecchia is an interesting example of the composite type of breakwater in which the rubble mound has been protected, and greatly reduced in volume and extent in deep water, by stepped courses of concrete blocks carried up from near the bottom of the mound (fig. 11). In all these cases, and in some other examples of similar construction, serious damage has occurred, largely due to the unequal settlement of the horizontally bedded courses of blocks. For this reason the Marseille type of sea face protection is to be preferred and is now generally adopted.

exposed situations of a small breach in the comparatively weak outer wall, leading to the scouring out of the rubble filling and progressive destruction, and the practice was abandoned. (In certain cases the rubble filling was replaced by solid hearting.)

Another cause of possible damage is due to the action of waves on the air which fills the interstices between the stones or blocks of mound and composite breakwaters. The violent compression of imprisoned air under a solid capping, or deck, exerts a destructive force which may blow up or displace the superstructure if its thickness and weight are not great enough to resist the pressure.

**Breakwaters in North America.**—Many breakwaters constructed for forming harbours on the sea coasts of the United States and Canada and in the Great Lakes are of the rubble mound type. The two detached breakwaters sheltering the old Delaware harbour made many years ago were of this type. They were united towards the end of the 19th century by closing the gap between them, the new work being similar in section to that

FIG. 13.—CROSS SECTION OF BREAKWATER, DELAWARE BAY HARBOUR OF REFUGE, U.S.A.

of the breakwater (fig. 13) formed in 1897-1901 for providing a harbour of refuge seaward of the original Delaware harbour. The breakwater, commenced in 1898, in San Pedro bay, Los Angeles, in a depth of 48ft. at low water, is of the same form. A simple mound construction was adopted in 1910 for the Colon breakwater (fig. 3), when the construction of the Panama canal made the port, naturally a bad one, a harbour of importance.

### (3) MOUND BREAKWATERS WITH SUPERSTRUCTURE BELOW LOW WATER

As the main object of this class of breakwater is to keep the mound below the zone of wave disturbance in severe storms, it is evident that the depth at which the superstructure is founded should vary directly with the exposure and inversely with the size of the materials forming the mound.

Though composite breakwaters are still occasionally constructed with a superstructure founded on a rubble mound at, or above, low water, as described in the preceding section, the practice of placing the foundations at a considerable depth has become more usual. In Italian harbours, for instance, whereas at the close of the 19th century practically all the then existing breakwaters were of the former type, the deep submerged vertical-wall type has been adopted for nearly all breakwater construction in deep water since 1900. French engineers have, however, continued to favour the earlier form of the composite breakwater, the Marseille design being the prototype of most of the deep water breakwaters built by them during the first quarter of the 20th century. They have, nevertheless, departed from this practice in the case of the later work carried out at Algiers, and it is probable that the future extension of the breakwater at Marseille, to form the Bassin du Phare, in a depth exceeding 100ft. will be similar to the Algiers design.

**Alderney.**—The depth at which wave action may adversely affect a rubble mound has been only very gradually realized. Thus in 1847 the Alderney breakwater, though fully exposed to the Atlantic ocean, was begun with a superstructure founded at low water upon a rubble mound. Within two years the foundations had to be carried 12ft. below low water. This construction was

adhered to up to close to the head, though the breakwater, completed in 1864, extended 4,700ft. from the shore into a depth of 130ft. at low tide, the spring rise being 18 feet. The recoil of the waves from the high superstructure wall brought about the degradation of the mound to a depth of 20 feet.

**Colombo.**—At Colombo, where the range of tide is only 2ft., the south-west breakwater (1875–85), which is exposed to the full force of the south-west monsoon, extends into a depth of 39ft. at low water. The superstructure was founded on a rubble mound 20ft. below low water. It is protected along its sea face by an apron of concrete in bags. The lesser depth of water and the lower superstructure, combined with the concrete bag protection, are factors which saved the breakwater from the failure which overtook that at Alderney where the exposure is similar. Nevertheless, the experience gained of the action of the sea on the south-west breakwater led to the north-west detached breakwater at Colombo, of similar type, and constructed at a later date in a somewhat deeper but less exposed situation, being built with the foundations of the superstructure on the rubble mound placed at a depth of 31ft. below low water (fig. 14). In the building of the outer arm extension of the south-west breakwater (completed 1912) a submerged wave breaker of 30-ton concrete blocks deposited pell-mell was constructed on the sea face of the upright wall (figs. 15 and 16), and this protection was extended along the whole of the sea face of the older part of the breakwater.

**Peterhead.**—The south breaker for the harbour of refuge at Peterhead, begun in 1888, extends into a depth of 57ft. at low water (*see HARBOURS*). For 1,000ft. from the shore it was built as an upright wall on a rocky bottom, but the outer portion consists of a superstructure wall of concrete blocks founded on a rubble base originally 30ft. below low water, increased after a storm in 1898 to 43 feet. The outer toe is protected by concrete blocks laid on the rubble mound. The northern breakwater at Peterhead (building 1928) is of the upright wall type on a rock foundation.

**Naples.**—The Ante-Murale breakwater at Naples (fig. 17) is a rubble mound in a depth which at the outer end exceeds 100 feet. The superstructure of horizontally coursed concrete blocks is founded 31ft. below sea level and is capped by mass concrete. Here the sea bed is firm and comparatively non-yielding and

FIG. 17.—CROSS SECTION OF THE ANTE-MURALE BREAKWATER AT NAPLES HARBOUR

special precautions were taken in building the rubble mound; consequently the structure has not suffered as a result of unequal settlement.

**Sloping-block System.**—A difficulty experienced in building a solid superstructure on the top of a rubble mound arises from the settlement of the mound which takes place when the weight of the wall comes on it. When the superstructure consists of horizontal courses of masonry or concrete blocks, irregular settlement is likely to occur, resulting in dislocation of the joints and sometimes fracture of blocks. The sloping-block (or "sliced-block") system, in which the blocks form a series of sloping sections, laid at an angle to the horizontal usually from  $67^{\circ}$  to  $74^{\circ}$ , was devised to meet this difficulty. The blocks are free to settle, slice by slice, on the mound and are usually joggled together on the sliding faces

by means of grooves in the blocks, filled by concrete in bags placed in position and rammed by divers, or by a groove and tenon moulded in the block faces (figs. 14 to 16, 18 to 20 and 24).

The settlement of the structure is sometimes accelerated by placing extra blocks temporarily on the top of the permanent blocks, thus increasing the load above the normal. Where a Titan crane is employed for setting the blocks, the weight of this assists

FIG. 18.—CROSS SECTION OF THE ORIGINAL BREAKWATERS AT MADRAS  
settlement. The mass concrete capping on top of the blocks should never be constructed until settlement as far as can be assured has taken place.

**Karachi.**—The first superstructure built on the sloping block system was at Karachi. The blocks were laid at an inclination of  $76^{\circ}$  in two rows of three superimposed blocks and were entirely unconnected. Consequently the sea, forcing its way in a storm between the two vertical rows, overturned some of the 27-ton top blocks and threw them on to the rubble mound. In effecting the necessary repairs the top blocks were connected by stone dowels.

**Madras.**—The superstructures of the Madras breakwaters, commenced in 1877 (fig. 18), were of similar construction to that at Karachi; but the blocks in each row were connected by a mortise and tenon joint with the blocks above it. The unconnected vertical joint between the two rows, however, led to the destruction of the greater part of the walls of the outer arms during a cyclone in 1881. In the subsequent reconstruction bond was introduced in the successive tiers of each sloping section and the upper blocks were cramped together. After settlement on the mound had ceased, a thick capping of mass concrete was laid on the top of the structure; and, finally, a mound of pell-mell concrete blocks was deposited on the rubble on the sea face of the wall to break the force of the waves and prevent undermining.

The harbour at Madras is constructed in a position of extreme exposure and the works have suffered severe sea damage on many occasions. The original harbour entrance on the east side between the ends of the two curved breakwaters was closed in 1910, partly on account of the serious range in the harbour, due to the position of the entrance, and also because of the rapid silting which was taking place (*see HARBOURS*). A new entrance was constructed on the north side of the harbour protected by a sheltering arm. This arm, as well as the new portion of the breakwater closing the old entrance, is of sloping block work on a rubble foundation protected by 30-ton wave-breaker blocks on the sea face (fig. 19). The outer portion of the sheltering arm was destroyed during a cyclone in Nov. 1916 and has since been reconstructed.

**Marmagão.**—The breakwater at Marmagão, a Portuguese harbour on the west coast of India, commenced in 1884, is somewhat similar to the later work carried out at Madras. The mound in this case is formed on a soft clay bed readily compressible (fig. 20).

**Colombo.**—At Colombo the superstructures of both the south-west and north-west breakwaters were built on the sloping block system in sections  $5\frac{1}{2}$ ft. thick at an angle of  $68^{\circ}$  (figs. 14 to 16). The blocks are bonded across each section and grooves are formed in the adjacent faces of the sections. The voids so formed were filled with concrete in bags after settlement on the mound had ceased. The same method of bonding and keying was adopted in the later work at Madras.

FIG. 19.—THE MODERN MADRAS BREAKWATERS: CROSS SECTION OF NORTH SHELTERING ARM AND BREAKWATER CLOSING OLD ENTRANCE

**Other Examples of Sloping Block Construction.**—The superstructure of the new Valparaiso breakwater extension (*see* below) makes use of sloping block work; and among other breakwaters of this type building in 1928 may be mentioned those at Port Elizabeth and Antofagasta (Chile), and the extension of the Table bay breakwater. In the case of the last named the

FIG. 20.—CROSS SECTION OF THE BREAKWATER AT MARMAGAO, INDIA

blocks are, however, laid direct upon the hard clay of the sea bed and not on a rubble mound.

**Hollow-block Construction.**—In the Granili breakwater at Naples, commenced in 1910, hollow concrete blocks each weighing under 100 tons, but measuring 30ft.  $\times$  16½ft.  $\times$  7½ft., were substituted for the smaller solid blocks used in the original work. The cavities in the blocks were filled with concrete deposited under water. The blocks being set one directly above another, five in height and in two rows, form separate piers free to settle independently. The two rows of blocks make up a superstructure 60ft. wide. The capping of solid masonry and concrete work above water level is constructed in separate sections covering only two piers of blocks to enable the masonry to follow the settling movements of the blocks.

The weak point of the hollow block system is the necessity of depositing unset concrete under water, always a difficulty and attended by uncertainty as to the quality of the concrete so treated. Apart from this possible source of weakness, the hollow block method of construction gets rid of the fear of displacement of solid concrete blocks set in horizontal bonded courses. It has been largely adopted in Italy, and to some extent in other countries, in situations of moderate exposure or where lengthy periods of calm weather can be looked for. At Genoa the Vittorio Emanuele III. breakwater (fig. 21), built after the construction of the Granili breakwater at Naples, is of similar type; but larger hollow blocks, which weigh up to 230 tons and extend the full width of the wall, were employed.

**Cyclopean Concrete Blocks.**—Following on their successful work with hollow blocks Italian engineers devised in 1923 a system of construction in which blocks of large dimensions, each extending the full width of the superstructure, are set to form pillars usually of three or four tiers in height. Blocks weighing from 200 tons to over 400 tons have been used in the building of breakwaters of this description, and for their handling floating lifting appliances have been devised which are of far greater capacity

than any previously employed. The blocks, known as Cyclopean, are nearly solid, each having small cavities for convenience of lifting, which are ultimately filled with concrete (*see* Albertazzi and Cagli, Int. Congress of Navigation, 1926, Paper 36).

The extension of the eastern jetty at Catania in Sicily is the first example of Cyclopean construction on a large scale, the blocks weighing 300 tons. Blocks of similar weight have been used in the new breakwater at Bari. The extensions of the Vittorio Emanuele III. breakwater and the Galliera mole at Genoa are (1928) being constructed with Cyclopean blocks. In these cases the weight of each block is restricted to 220 tons in order to make use of the existing floating cranes which had handled the earlier cellular blocks at that port. At Bengazi (Cirenaica) solid blocks, weighing 550 tons and constructed in a small dock, were floated into position by means of coupled pontoons between which a block, partly waterborne, was slung.

In the building of the Mustapha breakwater at Algiers, begun in 1927, blocks which weigh up to 418 tons are founded on a rubble mound at a depth of 49ft. (fig. 22), and are lifted and lowered into place by a floating portal crane of 450 tons lifting capacity mounted on two pontoons. The joint faces of the blocks are grooved and tenoned in the vertical planes.

**Caisson Walls in Composite Breakwaters.**—Caissons constructed of reinforced concrete or steel were employed in the building of the superstructures of composite breakwaters many years before the introduction of the hollow block and Cyclopean systems. The use of caissons is generally satisfactory when they can be founded directly on a firm and unerodible sea bed, but in several instances where this is not the case extensive damage

FIG. 21.—VITTORIO EMANUELE III. BREAKWATER AT GENOA. NOTE THE HOLLOW BLOCK CONSTRUCTION. BY PERMISSION OF THE CHIEF ENGINEER

has occurred. In any case it is a difficult matter to float, tow, sink and fill with concrete caissons of large dimensions.

**Bilbao.**—The composite breakwater at Bilbao harbour at the mouth of the River Nervion, begun in 1888, has probably been one of the most difficult to construct on account of its great exposure to the Atlantic waves. The original design consisted of a wide rubble mound up to about 16ft. below low water; a mound of concrete blocks up to low water; and a solid masonry superstructure. The repeated damage to this wall by successive winter storms led (in 1895) to the abandonment of the original design and the construction, on a widened rubble base, of a superstruc-

ture protected to some extent by the outlying concrete block mound. The modified superstructure was formed of iron caissons partially filled with concrete which were floated out, sunk in position and filled up with concrete blocks and mass concrete. The caissons, which measured about 43ft. in width across the breakwater, 23ft. in length and 23ft. in height, weigh about 1,400 tons when filled. They form the base of a concrete wall founded at half tide level and carried up to 8ft. above high water. Although some difficulties have been brought about by the settlement of the rubble foundation, these have been overcome and the breakwater has successfully resisted the attacks of the heavy Atlantic rollers (see *Churrua and the Port of Bilbao*, Bilbao, 1910).

**Other Examples of Caisson Construction.**—The mole of Zeebrugge (1900–09) (fig. 23), is an example of a breakwater, in a much less exposed situation than Bilbao, in the building of which caissons were used with not altogether satisfactory results, the work having suffered damage during construction. The caissons, of steel and reinforced concrete, are founded on a rubble mound at various depths up to 40ft. below low water. The largest caissons are 100ft. long and 38ft. wide (see *Mémoires, Société des Ingénieurs Civils de France*, Dec. 1904). Reinforced concrete caissons have also been used in building (1908–13) the two breakwaters at Bahia (Brazil), where the water is shallow and the position a sheltered one, and at Scheveningen in Holland. Their use in the construction of the Bizerta breakwater, begun in

BY COURTESY OF MESSRS. SCHNEIDER AND COMPANY

FIG. 22.—THE MUSTAPHA BREAKWATER, ALGIERS, OF CYCLOPEAN BLOCK CONSTRUCTION. THE CONCRETE BLOCKS WEIGH OVER 400 TONS

1899, was attended by failure and ultimately abandoned. The east breakwater extension at Barcelona, finished in 1909, had a superstructure wall formed up to water level by caisson monoliths. Nearly a mile of this wall was destroyed or damaged during a gale in 1920; but the failure was due not directly to the use of caissons but to inadequate width in the wall and the absence of protection of the inner toe of the superstructure. At Kobe, a Japanese port in a comparatively sheltered position, reinforced concrete caissons of large size have been used since 1910 in the construction of breakwaters on a soft and yielding sea bed. The caissons are founded on a rubble mound and protected by coursed block work both on the outer and inner faces.

**Valparaiso.**—One of the most interesting breakwater structures of the 20th century is that at Valparaiso, the first part of which was built in 1912–21 (see *Proc. Inst. C.E.*, vol. ccxiv., 1922). The breakwater is of composite construction; the inner section, 541ft. in length, consisting of horizontal coursed concrete blocks set on a submerged rubble mound at a depth of 20ft. and protected on the sea face by a pell-mell block wave-breaker of the Madras type (see above). The superstructure of the outer portion (fig. 24), 405ft. in length, consists of reinforced concrete caisson monoliths, which were floated over and sunk upon a rubble mound at 46ft. below mean level of the ocean. These monoliths are the largest which had been hitherto constructed in such a situation, each measuring 65½ft. long, 52½ft. wide at base and 49ft. in height, and were, after sinking, filled with mass concrete. The monoliths, as well as the blockwork of the inner section, are surmounted by a mass concrete superstructure and parapet wall. The outer portions of the breakwater were founded at a depth of

over 150ft., on a comparatively soft sea bed of clay and mud. The depth in which the Valparaiso breakwater has been built is greater than obtains in the case of any other marine structure and it is fully exposed to the northerly gales of the Pacific ocean.

An extension of the breakwater, 2,300ft. in length, in an easterly direction across Valparaiso bay, in depths as much as 180ft. in places, was commenced in 1923 and was still under construction

FIG. 23.—CROSS SECTION OF OUTER PART OF MOLE OF THE ZEEBRUGGE BREAKWATER

in 1928. For this extension sloping block work was substituted for caisson monoliths in the building of the superstructure, partly on account of the soft character of the sea bed in the silt of which it is estimated that the mound will sink considerably. The sloping blocks are joggled by pre-formed grooves and tenons on the sliding faces, and are surmounted by *in situ* concrete work as in the older structure. The lower part of the mound, up to a level of 66ft. below mean sea level, is of sand dredged by a powerful suction hopper dredger, and deposited on the sea bed, the flat slopes being protected by stone rubble.

**Timber Cribwork.**—The superstructures of composite breakwaters, built by the United States and the Canadian Governments in the Great Lakes, were often composed of timber cribs floated, like caissons, into position and sunk by filling them with rubble stone. The former cheapness of timber in those regions made this simple mode of construction economical in spite of the rapid decay of the timber. In the more modern examples the timber work is usually not carried higher than about 3ft. below water level, the upper parts being of concrete construction.

**Suitability of Composite Breakwaters to Deep Water Conditions.**—In view of the increased depth at which superstructures are now founded upon rubble mounds, causing the break-

FIG. 24.—CROSS SECTION OF THE VALPARAISO BREAKWATER (1912–21), SHOWING REINFORCED CONCRETE MONOLITH SUPERSTRUCTURE  
The sloping blocks used in building the superstructure of the extension (1927) are shown in the small plan on right

waters to approximate more and more to the upright wall type, it might seem at first sight that the rubble base might be dispensed with and the superstructure founded directly on the sea bed. Two circumstances, however, still render the composite form of breakwater indispensable in certain cases: (1) the great depth into which breakwaters have sometimes to extend, reaching about 60ft. below low water at Peterhead, 117ft. below mean sea level at Naples and even 180ft. at Valparaiso; and (2) the necessity, where the sea bottom is soft or liable to be eroded by scour, of a wide base between it and the upright superstructure.

The injuries to which composite breakwaters appear to have been specially subject must be attributed primarily to the greater exposure and depth of the sites in which they have been frequently constructed as compared with rubble mounds or upright walls; but the direct cause of damage and even destruction has in many cases been the insufficient depth at which superstructures have been founded. Upright walls, indeed, are not well suited for erection

BY COURTESY OF MESSRS. COODE, FITZMAURICE AND WILSON

FIG. 25.—CROSS SECTION OF SOUTH BREAKWATER, DOVER HARBOUR, ILLUSTRATING THE METHOD EMPLOYED IN THE CONSTRUCTION OF THE THREE BREAKWATERS AT DOVER HARBOUR

in waters of great depth owing to the increased pressure of air under which divers have to work in laying blocks or preparing foundations. In the case of simple rubble mounds, the very large quantity of materials required for a high mound with flat slopes makes that type unsuited to such situations. The ample depth at which superstructures are now commonly founded; the due protection of the outer toe; the adoption of improved systems of block construction, such as the sloping block or the Cyclopean; adequate bonding and keying of the blocks; and the dispensing in many cases with a high sheltering wall, render modern superstructures as stable as upright wall breakwaters of similar height. Nevertheless, the conditions of exposure being equal, superstructures require generally greater base width than upright walls of the same height, because the greater depth of water in which such composite breakwaters are built exposes them to larger waves.

#### (4) UPRIGHT WALL BREAKWATERS

The fourth type of breakwater is a solid structure founded directly on the sea bottom in the form of an upright, or nearly upright, wall with only a moderate batter or inclination from the perpendicular on each face. This type is limited to sites where the sea bed consists of rock, chalk, boulders or other hard material not subject to erosion by scour, and where the depth at high water does not exceed about 70 feet. When the foundations for an upright wall breakwater have to be levelled by divers, and the blocks laid under water by their help, the extension of such breakwaters into a considerable depth is undesirable on account of the increased pressure imposed upon diving (*q.v.*) operations. In the north breakwater at Peterhead (1928) the coursed concrete blocks were built on a rock foundation in 60ft. at low water, or about 71ft. at high water springs.

**Dover.**—The Admiralty pier at Dover was begun about the middle of the 19th century and is an early and notable example of an upright wall breakwater resting upon a hard chalk bottom. It was subsequently extended in connection with the works for forming a closed naval harbour at Dover, which works included the construction of an eastern breakwater and a detached south breakwater (see *Proc. Inst. C.E.*, vol. ccix., 1921). These are founded on a bottom, carried down to the hard chalk underlying the surface layer, levelled by men in diving-bells. The breakwaters are built of concrete blocks in bonded courses (fig. 25), the outer blocks above low water being faced with granite

masonry. The face blocks are joggled together, and above low water the blockwork is set in cement mortar and the vertical joints grouted up. The blocks were laid by Goliath travelling cranes running on temporary staging supported by clusters of timber piles driven into the chalk bottom. Four Goliaths on each staging were used for excavating, preparing foundations with diving-bells and block-setting.

The deepest foundation is 53ft. below low water springs. The rise of tide at springs being 18½ft., the average depth is thus approximately 66ft. at high tide, necessitating a pressure of about 30 lb. on the square inch, which is near the limit at which divers can work continuously, without injurious effects, in diving bells. The detached southern breakwater has a flush deck, but the Admiralty pier and the eastern breakwater have parapet walls. All the breakwaters are protected from scour along their outer toe by an apron of concrete blocks.

**Tyne Piers.**—The two breakwaters at the mouth of the River Tyne were originally commenced, about the middle of the 19th century, as composite breakwaters, the foundation level of the superstructure being placed at varying depths from near low water down to about 27ft. below low water in the case of the north pier. Towards the end of the century the north pier was severely damaged and breached as a result of the undermining of the foundation of the superstructure, brought about by the degradation of the rubble mound. The outer portion of this breakwater, about 1,500ft. in length, was reconstructed (1899-1909) on a straight line inside and under the shelter of the damaged curved part of the original breakwater (see *Proc. Inst. C.E.*, vol. clxxx., 1910). The reconstructed work is of the Dover type, the foundations, except near the inner end, being carried down to hard shale. All the exposed blocks are faced with granite and all blocks above low water are set in cement. A novel feature was introduced into the design with the object of preventing the

BY COURTESY OF MESSRS. COODE, FITZMAURICE AND WILSON

FIG. 26.—CROSS SECTION OF TYNE NORTH PIER AS RECONSTRUCTED, 1899-1908

sliding of one course of blocks over the course immediately below it; a check 6in. high, extending practically from end to end of the work, being provided in each course of blocks below low water (fig. 26).

**Granite-faced Blocks.**—It may be mentioned here that the use of granite masonry facing for concrete blocks in breakwater construction is unusual in modern work. The improvements which have been effected in concrete construction, its reliability when properly carried out and the impermeability of sound, well made concrete, have resulted in the gradual abandonment of masonry

construction in favour of the more economical concrete. In some French ports large blocks are still made of a rough masonry consisting of rubble stone set in a concrete matrix and forming a sort of coarse conglomerate. Where the local conditions as to materials are favourable this form of construction is very economical.

**Concrete-bag Foundations.**—The levelling of the foundations for an upright wall breakwater is costly and tedious, even in

BY COURTESY OF THE CHIEF ENGINEER, RIVER WEAR COMMISSION

FIG. 27.—CROSS SECTION OF BREAKWATER NEAR OUTER END OF ROKER PIER, SUNDERLAND

chalk; and the expense and delay are enhanced where the bottom is hard rock. In constructing two breakwaters at the entrance to Aberdeen harbour on a bottom of granite, in 1870–77, bags of freshly mixed concrete were laid on the sea bed; and these bags, by adapting themselves to the rocky irregularities, obviated levelling the bottom. The bags each held 50 tons and were deposited from hopper barges towed out to the site. They were used for the construction of the breakwaters up to low water, mass concrete being employed for those portions above that level. Bags holding 100 tons were used subsequently at Newhaven in constructing a breakwater on a chalk foundation. Still later the two breakwaters sheltering the approach to the River Wear and the Sunderland docks were built, on a sea bed of marl rock, with a foundation mound of concrete in bags holding 56 to 116 tons deposited from hopper barges. The more exposed northern (Roker) breakwater (fig. 27) is devoid of a parapet, the deck being 11 ft. above high water. The south breakwater has a parapet wall. Bag work was also used in constructing the superstructure of the eastern breakwater of Bilbao harbour below low water, where the rubble mound is of moderate height; but this application of the system appears less satisfactory, as settlement of the superstructure on the mound would produce cracks in the set concrete of the bags.

**Caisson Monoliths.**—Caisson monoliths have also been used in constructing the foundations of upright wall breakwaters, and some of the Heligoland moles, demolished after the World War, were built on this system (see *Proc. Inst. C.E.*, vol. 220, 1926). Caissons, sunk by means of compressed air through the overlying sand and gravel into a foundation of hard chalk, were employed in constructing the lower portions of the vertical walls of the breakwaters at Dieppe where the tidal range is 30 ft. at springs.

#### GENERAL

**Block-setting Cranes.**—The blocks used in breakwater construction are often laid in place by overhanging, block-setting cranes, called "Titans," which travel along the completed portion of the breakwater and deposit the blocks in advance on the mound levelled by divers. The cantilever superstructure of the Titan crane is supported centrally on a ring of rollers, set on the top of the travelling pedestal or portal, so that it can revolve and pick up blocks from behind the crane and deposit them at the side of the breakwater as well as in advance of the finished work (fig. 9). The large Titan at Peterhead deposits 50-ton blocks at a maximum radius of 100 ft.; that used at Fishguard had a radius of 125 feet. Titans are generally preferred for block setting by British engineers and have the important advantage, in exposed situations, that they can be moved back into shelter in stormy weather. The weight of the Titan also contributes to the consolidation of the rubble mound. When a Titan crane has been used

in the building of a breakwater it should be retained, on the completion of the work, in some convenient position, as well as permanent rails for its travel along the breakwater. The crane is then available for use if repairs have to be carried out involving the lifting of large blocks. Such maintenance work must always be anticipated in the case of breakwaters of the mound and composite types.

Gantry cranes (called "Goliaths") travelling on temporary staging, are sometimes employed for block setting when the depth of water is not too great. As several cranes can be employed at the same time more rapid progress can be made than with a single Titan crane working at the end of a breakwater; but the expenditure on plant and staging involved by this method of construction is much greater than when a Titan crane is used. At many Mediterranean and other ports, where a continuance of calm seas over considerable periods of time is usual, floating plant is commonly employed for block setting.

**Breakwater Heads.**—The end of a breakwater is frequently subjected to intense scour which may extend to a considerable depth. The foundations of a superstructure wall at the head of a breakwater are therefore sometimes placed at a lower level than the rest of the work; the base of the superstructure is often made wider; and the rubble mound, if there be one, is extended and the protection by apron blocks increased. Moreover, in solid blockwork construction some special means must be adopted to finish off and protect the concrete blocks where the ordinary section of the work terminates.

Various methods have been adopted for the construction of the heads of breakwaters. In some cases large steel caissons, circular or rectangular in plan, have been sunk on or into the sea bed or mound to form a foundation brought up above water level and afterwards filled with concrete blockwork or mass concrete. The blockwork of the main portion of the breakwater is subsequently built up to, and makes junction with, the caisson head. The head of the Colombo south-west breakwater is an early instance of a steel caisson founded on a rubble mound; and a circular steel caisson sunk to below sea-bed level was used for the head of the north sheltering arm at Madras (see *Proc. Inst. C.E.*, Selected papers, 1926). In other instances reinforced concrete caissons have been employed instead of steel caissons. Where caissons are not used the end of the breakwater is often built of specially constructed and keyed blocks in the form of a roundhead or some other enlargement of the normal section. This plan is commonly adopted in the construction of upright wall breakwaters on firm foundations such as the Dover breakwaters and the north pier at Tynemouth described in the preceding section. It has also been the Gibraltar moles (see *Proc. Inst. C.E.*, vol. cxcvii., 1924) completed in 1905.

Some form of lighthouse (*q.v.*) or port light for the guidance of mariners is usually established on a breakwater head.

**Parapet Walls.**—It has been the general practice to provide a shelter or parapet wall on the sea face of breakwater superstructures. In many cases a tunnel-way or passage is formed in the parapet for access in stormy weather to the light at the head of the breakwater. In several important examples, however, such as the island breakwater at Dover and the Colombo western breakwaters, no parapet wall is provided. Moreover, sheltered access can be provided by a subway under the deck of the breakwater as at Sunderland. In special cases where a breakwater has to serve as a quay, like the Admiralty pier at Dover, a high parapet wall is essential; but in most cases, in order to increase the stability of the structure, it would seem advisable to keep the parapet very low or to dispense with it altogether. This course is particularly expedient in very exposed sites, as a high parapet intensifies the shock of the waves against a breakwater and their erosive recoil.

**Small Breakwaters.**—The breakwaters and protective piers which are constructed at small harbours such as fishery harbours and ports of secondary importance are frequently built in comparatively shallow water and sheltered positions. In their construction the principles which have been set out in the foregoing paragraphs are applicable, *mutatis mutandis*. Many small upright

wall breakwaters have been constructed in a moderate depth of water on a hard bottom of rock, chalk or boulders, by erecting timber framing in suitable lengths, lining it inside with jute cloth and then depositing concrete below low water in closed hopper skips. The portion of the breakwater above low water is then raised by tide work with mass concrete or masonry.

A form of breakwater, frequently adopted in past times for comparatively sheltered positions in no great depth of water where the sea bed consisted of sand or other soft material, is the cribwork pier. This type of structure was commonly formed of two rows of timber piles driven in the sea bed and connected together by ties or bracing, to which were fixed horizontal timber runners with spaces between them. The crib so formed was filled in with large stone rubble.

**Cost of Breakwaters.**—The expense involved in the construction of breakwaters varies within wide limits. The degree of exposure of the site; the depth of water; the facilities for obtaining materials and labour and their cost, vary so much in different cases as to make comparison fallacious. The following figures of the average cost per lineal foot of typical breakwaters illustrate the wide variation. It should be noted that from 50% to 100% must be added to pre-war cost figures to make them comparable with post-war conditions.

| Breakwaters built before 1914              |       |                                 |                                   |
|--|-------|---------------------------------|-----------------------------------|
| Place.                                     | Type. | Average depth of water at H. W. | Approximate cost per lineal foot. |
|  |       | ft.                             | £.                                |
| Plymouth . . . . .                         | 1     | 59                              | 290                               |

| Casablanca . . . . .                       | 2     | 60                              | 250                               |

**Time Occupied in Building Breakwaters.**—The construction of most of the breakwaters described in this article has occupied many years; sometimes twenty and even thirty or forty years. An advance of 150 or 200ft. in the course of a season's work is often regarded as satisfactory. Generally speaking an increase in the rate of building involves a larger expenditure for a given length of structure.

**BIBLIOGRAPHY.**—For general principles of design and descriptions of 19th century construction see L. F. Vernon-Harcourt, *Harbours and Docks* (2 vols. Oxford, 1885); T. Stevenson, *The Design and Construction of Harbours* (1886); W. Shield, *Harbour Construction* (1895); Quinette de Rochemont, *Cours de Travaux Maritimes* (3 vols. 1900); C. de Cordemoy, *Les Ports Modernes* (2 vols. 1900); and, particularly for Italian breakwaters, *Ports Maritimes de l'Italie* (Milan, 1905; French and Italian eds.). G. de Joly and C. Laroche, *Travaux Maritimes*, vols. i. and ii. (1921-22), is a good modern work. Brysson Cunningham, *Harbour Engineering* (3rd ed., 1928), also contains references to more recent work. The writings of Smeaton, Telford and Sir John Rennie are of great historical interest in connection with early construction. The *Proceedings* of the International Navigation Congresses include many important papers on breakwater design and construction, especially those of the congresses at Milan (10th, 1905),

Philadelphia (12th, 1912) and Cairo (14th, 1926). A good and well illustrated description in English of earlier Italian breakwaters is L. Luiggi's *Recent Breakwaters in Italy* (Int. Maritime Congress, London, 1893). E. Quellenec's *Memoir* (I. N. C., Cairo, 1926) is an excellent résumé of modern Continental practice. Complete bibliographic lists are issued periodically (since 1908) by the International Association of Navigation Congresses, Brussels. See also *Proceedings Inst. C.E. and Mémoires, Société des Ingénieurs Civils de France*. (N. G. G.)

**BRÉAL, MICHEL JULES ALFRED** (1832-1915), French philologist, was born on March 26 1832, at Landau in Rhenish Bavaria, of French parents, and died in Paris on Nov. 25 1915. After studying at Weissenburg, Metz and Paris, he entered the École Normale in 1852. In 1857 he went to Berlin, where he studied Sanskrit under Bopp and Weber. On his return to France Bréal entered the department of oriental mss. at the Bibliothèque Impériale. In 1864 he became professor of comparative grammar at the Collège de France.

His principal works are *L'Étude des origines de la religion Zoroastrienne* (1862); *Hercule et Cacus* (1863), in which he disputes the principles of the symbolic school in the interpretation of myths; *Le Mythe d'Oedipe* (1864); *Les Tables Eugubines* (1875); *Mélanges de mythologie et de linguistique* (2nd ed., 1882); *Dictionnaire étymologique latin* (1885); *Essai de Sémantique* (1897), on the signification of words, translated into English by Mrs. H. Cust, with preface by J. P. Postgate.

THE BREAM, A FISH THAT INHABITS SLOW RUNNING RIVERS AND PONDS

**BREAM** (*Abramis brama*), a carplike fish with a deep, compressed body and a long anal fin. It is found in the rivers of Europe and northern Asia, in lakes and sluggish streams; the record weight for England is 17 lb. A related species, the White Bream (*A. blicca*) is much smaller. The name is also given

to the Sea Brems (*Sparidae*) and in the United States to the golden shiner (*A. chrysroleucus*) and others of the carp family.

**BREAST**, the term properly confined to the external projecting parts of the thorax in females, which contain the mammary glands (for anatomy, and diseases, see MAMMARY GLAND); more generally it is used of the external part of the thorax in animals, including man, lying between the neck and the abdomen.

**BREASTED, JAMES HENRY** (1865- ), American orientalist and historian, was born at Rockford, Ill., on Aug. 27, 1865. After graduating from North-western college (now North Central college) in 1888 he studied at Chicago theological seminary, Yale university and the University of Berlin. Beginning at the University of Chicago in 1894 as an assistant in Egyptology, he became professor of Egyptology and Oriental history in 1905, and director of the Oriental museum. He then directed an archaeological expedition in Egypt and the Sudan (1905-07). Meantime, by commission of the royal academies of Germany in 1900, he had been appointed on a mission to the museums of Europe to copy and arrange the Egyptian inscriptions in those museums for the first exhaustive Egyptian dictionary. In 1919, with funds supplied by John D. Rockefeller, Jr., he organized the Oriental institute at the University of Chicago as a scientific laboratory, the first of its kind, for investigating the early career of man and studying the history of ancient civilization. As first director of the institute he led an expedition to the Near East in 1919-20, subsequently organizing a series of five expeditions extending from the Black sea to Upper Egypt, with headquarter buildings in Asia Minor (Hittite expedition), Palestine (Armageddon expedition) and Luxor (Epigraphic expedition). He is editor of the institute's publications, appearing in three series. As a result of his representations to John D. Rockefeller, Jr., in 1925, the latter authorized him to offer the Egyptian Government the sum of \$10,000,000 for establishing an Egyptian museum and an archaeological research institute in Cairo. Although never declined, the acceptance of this offer was so delayed that it was consequently withdrawn. In 1927 he drew the same donor's attention to similar needs in Palestine and was authorized to offer the Palestine Government the sum of \$2,000,000 for a new archaeological museum at Jerusa-

lem. This offer was accepted and the gift was duly made. In 1919 he was elected president of the American Oriental Society, and in 1927 president of the American Historical Association.

He has published, among other works, *De Hymnis in Solemn sub Rege Amenophide IV., Conceptis* (1894); *A New Chapter in the Life of Thutmose III.* (1900); *Ancient Records of Egypt* (1906-07); *A History of Egypt* (1906; also French, German and Russian editions, and editions for the blind); *The Monuments of Sudanese Nubia* (1908); *Development of Religion and Thought in Ancient Egypt* (1912; French and German translations in preparation); *Ancient Times* (1915; also Swedish, Arabic and Malay editions), re-edited as *The Conquest of Civilization* (1926); *Survey of the Ancient World* (1919); *History of Europe, Ancient and Medieval* (with J. H. Robinson, 1920); *The Oriental Institute—A Beginning and a Program* (1923); *Oriental Forerunners of Byzantine Painting* (1924); *The Conquest of Civilization* (1926).

See George Ellery Hale, "The Work of an American Orientalist," *Scribner's Magazine*, vol. lxxiv., p. 392-404 (1923).

**BREASTPLATE**, in ancient armour, a plate of iron, steel or other metal, so fastened to protect the wearer's chest and front of the body in battle. Breastplates are still worn by the Household Cavalry in full dress, e.g., when on duty at the Horse Guards, London.

**BREASTWORK**, in military language, artificial cover from enemy fire built up of logs, sandbags, etc., above ground level. In swampy ground or woods it is commonly employed instead of trenches.

**BREAUTÉ, FALKES DE** (d. 1226), military adventurer, was one of the foreign mercenaries of King John of England, from whom he received in marriage the heiress of the earldom of Devon. On the outbreak of the Barons' War (1215) the king gave him the sheriffdoms of six midland shires and the custody of many castles. In 1217 he helped the royalist party of Henry III. to win a decisive victory at Lincoln, over Louis, the French claimant to the throne. But after the death of William Marshal, earl of Pembroke, Falkes joined the feudal opposition in conspiring against the justiciar, Hubert de Burgh. Deprived in 1223 of most of his honours, he took part in a rebellion in 1223-24. In 1224, he went into exile. He failed to obtain a pardon through the mediation of Pope Honorius III. and died at St. Cyriac in 1226.

**BIBLIOGRAPHY.**—See Shirley, *Royal Letters*, vol. i.; the *Patent and Close Rolls*; Pauli, *Geschichte von England*, vol. i., p. 540-545.

**BRECCIA**, in petrology, the name given to rocks consisting of angular fragments embedded in a matrix. They may be composed of any kind of material, and the matrix, which usually corresponds to some extent to the fragments it encloses, may be siliceous, calcareous, argillaceous, etc. The distinctive character of the group is the sharp-edged and unworn shapes of the fragments; in conglomerates the pebbles are rounded and water-worn. Breccias may originate in many ways. Some are formed by ordinary processes of atmospheric erosion; frost, rain and gravity break up exposed surfaces of rock and detach pieces of all sizes; in this way scree are formed at the bases of cliffs, and barren mountain-tops are covered with broken debris. If such accumulations are changed into hard rock by pressure cementation they make typical breccias. Caves, coral reefs and volcanic regions are other frequent sources.

Another group of breccias is due to crushing; these are produced in fissures, faults and veins, below the surface, and may be described as "crush-breccias" and "friction-breccias." Very important and well-known examples of this class occur as vein-stones, which may be metalliferous or not. A fissure is formed, probably by slight crustal movements, and is subsequently filled with material deposited from solution (quartz, calcite, barytes, etc.). Very often displacement of the walls again takes place, and the infilling or "veinstone" is torn apart and brecciated. It may then be cemented together by a further introduction of mineral matter, which may be the same as that first deposited or quite different. Other crush-breccias occurring on a much larger scale are due to the folding of strata which have unequal plasticities. Great masses of limestone in the Alps, Scottish highlands, and all regions of intense folding are thus converted into breccias. Cherts frequently also show this structure; igneous rocks less commonly do so; but it is perhaps most common where there have been thin-bedded alternations of rocks of different character, such

as limestone and dolerite, limestone and quartzite, shale or phyllite and sandstone. Fault-breccias closely resemble vein-breccias.

A third group of breccias is due to movement in a partly consolidated igneous rock, and may be called "fluxion-breccias." Lava streams, especially when they consist of rhyolite, dacite and some kinds of andesite, may rapidly solidify, and then become exceedingly brittle. If any part of the mass is still liquid, it may break up the solid crust by pressure from within and the angular fragments are enveloped by the fluid lava. When the whole comes to rest and cools, it forms a typical "volcanic fluxion-breccia."

(J. S. F.)

**BRECHIN**, royal, municipal and police burgh, Forfarshire, Scotland, on the left bank of the South Esk, 7½ m. W. of Montrose, a station on the loop line of the L.M.S. Railway from Forfar to Bridge of Dun. Pop. (1931) 6,838. Brechin was the site of a Culdee abbey. The Danes are said to have burned the town in 1012. David I. erected it into a bishopric in 1150, and it is still a see of the Episcopal Church of Scotland. In 1452 the earl of Huntly crushed the insurrection led by the earl of Crawford at the battle of Brechin Muir, and in 1645 the town and castle were harried by the marquess of Montrose. James VI. gave a grant for a hospital; this still supplies funds for charity. No trace remains of the old walls and gates. Ancient structures include a very early two-arched stone bridge, Holy Trinity cathedral (13th century) much altered, and near by a round tower built about A.D. 1000. It is 86½ ft. high, has at the base a circumference of 50 ft. and a diameter of 16 ft., and is capped with a hexagonal spire of 18 ft., which was added in the 15th century. This type of structure is common in Ireland, but the only Scottish examples are those at Brechin, Abernethy in Perthshire, and Egilshay in the Orkneys. Brechin castle played a prominent part in the Scottish War of Independence. In 1303 it withstood for 20 days a siege in force by the English under Edward I., surrendering only when its governor, Sir Thomas Maule, had been slain. From the Maule family it descended to the Dalhousies. Its library contains Burns' correspondence with George Thomson and several cartularies, including those of St. Andrews and Brechin. In the Vennel (alley or small street) are ruins of the *maison dieu* or *hospitium*, founded in 1256 by William of Brechin. The industries include linen manufactures and flax-spinning, bleaching, rope-making, distilling, iron-founding and paper-making. Brechin unites with Arbroath, Forfar, Bervie and Montrose to return one member to parliament.

**BRECKENRIDGE**, a city of north-eastern Texas, U.S.A., 110 m. W. of Fort Worth; the county seat of Stephens county. It is served by the Cisco and Northeastern, the Wichita Falls and Southern, and the Wichita Falls, Ranger and Fort Worth railways. The population in 1920 was 1,846; in 1930 by the Federal census it was 7,569. It is in the midst of an oil-field which was discovered in 1918. The city was settled in 1876 and incorporated in 1919.

**BRECKINRIDGE, JOHN CABELL** (1821-1875), American soldier and political leader, was born near Lexington, Ky., on Jan. 21, 1821. He was a member of a family prominent in the public life of Kentucky and the nation. His grandfather, John Breckinridge (1760-1806), was a United States senator from Kentucky in 1801-05 and attorney-general in President Jefferson's cabinet in 1805-06.

John Cabell Breckinridge graduated in 1838 at Centre college, Danville, Ky., continued his studies at Princeton, and then studied law at Transylvania university, Lexington, Kentucky. He practised law in Frankfort, Ky., in 1840-41 and in Burlington, Ia., from 1841 to 1843, and then returned to Kentucky and followed his profession at Lexington. In 1847 he went to Mexico as major in a volunteer regiment. In 1849 he was elected a Democratic member of the Kentucky legislature; in 1851-55 he served in the national House of Representatives. In 1856 he was chosen vice-president of the United States on the Buchanan ticket, and although a strong pro-slavery and states rights man, he presided over the Senate with conspicuous fairness and impartiality during the trying years before the Civil War. In 1860 he was nominated for the presidency by the pro-slavery seceders

from the Democratic national convention, and received a total of 72 electoral votes. As vice-president and presiding officer of the Senate, it was his duty to make the official announcement of the election of his opponent, Lincoln. He succeeded John J. Crittenden as United States senator from Kentucky in March 1861, but having subsequently entered the Confederate service he was expelled from the Senate in Dec. 1861. As brigadier-general he commanded the Confederate reserve at Shiloh, and in Aug. 1862 he became major-general. On Aug. 5 he was repulsed in his attack on Baton Rouge, but he won distinction at Stone River (Dec. 31, 1862-Jan. 2, 1863). He took part in the battle of Chickamauga, defeated Gen. Franz Sigel at Newmarket, Va., on May 15, 1864, and then joined Lee and took part in the battles of Cold Harbor June 1 and 3. In the autumn he operated in the Shenandoah Valley, and with Early was defeated by Sheridan at Winchester on Sept. 19. In Jan. 1865 he became secretary of war for the Confederate States. At the close of the war he escaped to Cuba, and thence to Europe. In 1868 he returned to the United States and resumed the practice of law at Lexington, Ky., where he died on May 17, 1875.

**BRECON** or **BRECKNOCK (ABERHONDDU)**, cathedral town, municipal borough and capital of Breconshire, Wales. Population (1931) 5,334, situated at the confluence of the Honddu with the Usk near the centre of the county. Its site commands routes from Builth in the north, Llandovery in the west, Merthyr and Crickhowell in the south, and Knighton and Hay in the east. About 3m. W. of the town is the famous Roman station known as "Y Gaer" and as is so often the case, Brecon has continued the importance of the nodal site selected by the Romans. From the ruins of the Roman Fort, it is said, Bernard de Newmarch built the original Norman Castle in 1092. Its history was a stormy one as was the case with all castles that were outposts near the Welsh Hills. Bernard subsequently founded, near the castle, the Benedictine priory of St. John, which he endowed and constituted a cell of Battle Abbey. Nothing remains of the original church except portions of the nave walls, but the rebuildings of the first half of the 13th century and of the 14th century gave beautiful Early English and decorated additions and made the edifice one of the finest churches in Wales. In 1923 it was made the cathedral of the newly constituted diocese of Swansea and Brecon.

Around the original castle and priory a small mediaeval town grew up, and its inhabitants received a series of charters from the de Bohuns, into which family the castle and lordship passed, the earliest recorded charter being granted by Humphrey, 3rd earl of Hereford. The town became one of the chief centres of trade in South Wales, and a sixteen days' fair, still held in November.

A Dominican friary was established to the south-west of the town and was refounded by Henry VIII. in 1542 as a collegiate church and school. This institution is now known as Christ's College. The nodal site of the town offered special facilities during Tudor economic developments for establishment of trade guilds as well as a Guild Hall. The guilds were formerly five in number, the chief industries being cloth and leather manufacture. There are five ancient fairs for stock, and formerly each of them was preceded by a leather fair. Further charters were granted by Mary in 1536 and again by Elizabeth. Brecon destroyed its castle to preserve its neutrality during the Civil Wars. The subsequent centuries were periods of social life and bustle for the now important capital of the county. The borough came under the Municipal Corporations act in 1835. A college for the training of Congregational Ministers was established in 1869.

By a statute of 1535 Brecon elected a member to represent it in parliament, a right it retained until it was merged in the county representation in 1885. It is now (since 1918) merged in the representation of the joint counties of Brecon and Radnor.

**BRECONSHIRE** or **BRECKNOCKSHIRE**, an inland county in south Wales, and fourth largest in all Wales, bounded on the north-west by Cardigan, on the north and north-east by Radnor, on the east and south-east by Monmouth, on the south by Glamorgan, and on the west by Carmarthen.

**Physical Conformation.**—With the exception of the Vale

of Usk at Crickhowell the county is almost encircled by mountains. To the north a range of barren hills, known as Mynydd Eppynt, stretches right across the county in a north-easterly direction towards Builth, beginning with Mynydd Bwlch y Groes (1,450ft.) near Llandovery. These hills are composed of the oldest rocks in the county, the Llandeilo shales, with their volcanic outflows (often containing mineral springs, as at Llanwrttyd and Builth) as well as the Bala beds, which, with the succeeding lower and upper Llandovery shales, sandstones, and conglomerates, form the sparsely populated sheep walks of the north part of the county. To the south-east of this region a narrow outcrop of Llandovery, Wenlock, and Ludlow sandstones and mudstones follows. The remainder and greater part of the county is occupied by the gently inclined old red sandstone, largely hill country, the highest point of which, north of the Usk, is Pen y Gader (2,624ft.) between Talgarth and Llanthony, where the lower marls and cornstones of the old red sandstone form the much dissected plateau of the Black mountains. The ring of hills is continued south of the Usk by the Brecon Beacons, composed mainly of the conglomeratic upper beds of the old red sandstone, weathered into many escarpments and plateaux. The highest point is Pen y Fan or Cadair Arthur (Arthur's Chair) (2,910ft.). In the extreme south-west of the county the ring of hills is completed by the Carmarthen Van, the highest point of which, Van Brycheiniog (2,632ft.), is in the county. The extreme southern boundary is formed by the scarps and moorlands of the carboniferous limestone and millstone grit, while the lowest beds of the coal measures (much folded) are reached in the upper Tawe and Neath valleys and near Brynmawr.

**Drainage System.**—The most distinctive feature of the drainage system is the valley of the Usk. The river rises in the Carmarthen Van in the west and flows nearly due east, dividing the county into two nearly equal portions. It also collects numerous streams from the Beacons on the south and the Eppynt in the north. The most important tributary streams are the Tarell and the Honddu. The confluence of the latter with the Usk marks the site of Brecon—the county town. Another river of the eastward drainage is the Wye, which forms the northern boundary of the county from Rhayader to Hay. A portion of the upper Towy, flowing north-east to south-west, following the line of the Eppynt, forms the county boundary on the north-west. The southern section has the upper reaches of the Taff, Neath, and Tawe, all of which ultimately flow southwards to the Bristol channel as part of the general south and south-westerly drainage system of Wales. There is evidence that the region was heavily glaciated, and much boulder clay is found in the lower valley lands and striated pebbles and boulders occur at a great height on the Black mountains. The porous rocks of Breconshire constitute one of the best water-producing areas in Wales, and many industrial centres are supplied from reservoirs in this county.

**History.**—As usual the earliest remains of man are on the high ground. Later the Usk and Wye valleys became especially important as ways through the mountains from the English border. On the spurs of the moorland overlooking the valleys are many hill-top camps. An interesting site is the artificial island in Llangorse lake (Llyn Safaddan) in the east of the county at the foot of the Black mountains, where traces of lake dwellings were discovered in 1869. The conquest of the district by the Romans was effected about A.D. 75–80. Their main purpose was to keep open valley lines of communication through their fortified nodal sites, such as the one three miles out of the present town of Brecon excavated in 1925–26 by the officers of the National Museum of Wales (see *Y Cymmrodor*, vol. xxxvii., 1926). Smaller forts were established on roads leading from this fort towards Neath and Crickhowell. On the departure of the Romans, the hill tribes and other raiders seem to have regained possession of the Usk valley under Brychan, who became the ancestor of one of the three chief tribes of hereditary Welsh saints. His territory (named after him Brycheiniog, whence Brecknock) lay wholly east of the Eppynt range, for the lordship of Buallt, corresponding to the modern hundred of Builth, to the west, remained independent, probably till the Norman

invasion. Most of the older churches of central Brecknockshire were founded by or dedicated to members of Brychan's family.

From the middle of the 8th century to the 10th, Brycheiniog proper, with its valley-ways open to the English plain, often bore the brunt of Mercian attacks, and many of the castles on its eastern border had their origin in that period. Subsequently, when Bernard de Newmarch and his Norman followers obtained possession of the country in the last quarter of the 11th century, these were converted into regular fortresses. Bernard himself built a castle at Talgarth on the Upper Wye, but in 1091 he moved southwards and, having defeated Bleddyn Ab Maenarch, he established himself at Brecon, which he made his *caput baroniae*. Brycheiniog was then converted into a lordship marcher and passed to the Fitzwalter, the de Breos, the Bohun, and the Stafford families in succession, remaining unaffected by the statute of Rhuddlan (1282), as it formed part of the marches, and not of the principality of Wales.

The Irfon valley, near Builth, was, however, the scene of the last struggle between the English and Llewelyn, who in 1282 fell in a petty skirmish in that district. Raids from the hills were frequent and Glyndwr (Glendower *q.v.*), at the head of a band of tribesmen, marched to Brecon in 1403.

Upon the attainder of Edward, duke of Buckingham, in 1521, the lordship of Brecon with its dependencies became vested in the Crown. In 1536 it was grouped with a whole series of petty lordships marcher and the lordship of Builth to form the county of Brecknock with Brecon as the county town, and the place for holding the county court. The most important mediaeval monastic house was the priory of St. John the Baptist, founded by Bernard de Newmarch at Brecon in the 11th century.

This county became famous for its wool in the later middle ages and attracted large numbers of continental weavers at different times, some of whom were refugees forming part of an intellectual *élite*. John Penry (1559-93), born at Llangammarch in the north-west of the county, was typical of the spirit of Puritanism that characterized this region, which developed strong points of view in religion, as is shown by the early importance of the Quakers and later of the Baptists. Later Howell Harris (1714-73), one of the most fiery leaders of the Methodist revival, was a native of the county.

**Industries.**—The county's one-time agricultural prosperity is indicated by an agricultural society dating from 1755, the oldest in Wales. Agriculture is still the chief occupation, and the county is chiefly pastoral. The breeding of cobs and ponies, as in Cardiganshire, is also important. The upper reaches of the Swansea and Neath valleys are important areas on the anthracite coalfield, while bituminous coal is mined in the south-east corner near Brynmawr. There are also limestone, fire clay, and cement works on the outcrop of the carboniferous limestone.

**Railways and Communications.**—The L.M.S.R. from Craven Arms to Swansea and from Hereford to Swansea runs through the county, effecting junctions with the G.W.R. at Builth (old Cambrian line), Three Cocks (mid-Wales line), Talyllyn (Merthyr and Newport line), and at Colbren (Neath and Brecon line). Brynmawr in the south-east is connected by L.M.S.R. with Abergavenny and with Pontypool and G.W.R. with Newport. Brecon is also connected with Newport by the Brecknock and Abergavenny canal (35m.), which was completed in 1801. The Swansea canal and that of the Vale of Neath have also their northern terminals in the county, at Ystradgynlais and Abernant respectively. The main roads are probably the best in south Wales, and nodal sites such as Brecon and Builth are coming into prominence in this respect.

**Area and Administration.**—The area of the ancient county is 475,224 acres and the administrative county 469,301 acres. The population (1931) was 57,771. The only municipal borough is Brecon, which is the county town, pop. (1931) 5,334. The other urban districts are Brynmawr (7,247), Builth Wells (1,663), Hay (1,509) and Llanwrtyd (742). The county forms part of the south Wales circuit and the assizes are held at Brecon. It has one court of quarter sessions and is divided into ten petty sessional divisions. There are 94 civil parishes, while the eccle-

siastical parishes or districts wholly or in part within the county number 70, of which 67 were until 1923 in the diocese of St. David's but are now in the newly constituted diocese of Swansea and Brecon, the remaining three being in the diocese of Llandaff. Brecon is the site of the new cathedral. The county is not divided for parliamentary purposes and until 1918 returned one member to parliament; since that date its representation is merged with that of the entire county of Radnor.

**BREDA**, town, province of North Brabant, Holland, at the confluence of the canalized rivers Merk and Aa. Pop. (1925) 30,670. Breda was in the 11th century a direct fief of the Holy Roman empire, its earliest known lord being Henry I. (1098-1125), in whose family it continued, until Alix, heiress of Philip (d. 1323), sold it to Brabant. It passed ultimately to William I. (1533-84), the first stadtholder of the Netherlands. Breda obtained municipal rights in 1252, but was first surrounded with walls in 1534 by Count Henry of Nassau, who also restored the old castle, originally built by John of Polanen in 1350. It remained until the 19th century the most important of the line of fortresses along the Meuse. Captured by the Spaniards in 1581, in 1590 it fell again into the hands of Maurice of Nassau. Its surrender to the Spaniards (1625) after a siege, is the subject of the famous picture by Velasquez in the Museo del Prado in Madrid. In 1637 Breda was recaptured by Frederick Henry of Orange, and in 1648 it was finally ceded to Holland by the treaty of Westphalia. It was the residence, during his exile, of Charles II. of England. In 1696 William, prince of Orange and king of England, built the new castle, now a military academy. During the wars of the French Revolution, it was taken by Dumouriez in 1793, evacuated soon after and retaken by Pichegru in 1795. In 1813, the citizens of Breda again made themselves masters of the town. It has been the scene of various political congresses, e.g., in 1575 a conference was held here between the ambassadors of Spain and those of the United Provinces; in 1667 a peace was signed by England, Holland, France and Denmark; and by the same Powers in 1746-47. The town has a fine quay, town hall and park. The principal Protestant church is a Gothic building (13th century), with a fine tower, and a choir (1410).

**BREDAEL, JAN FRANS VAN** (1683-1750), Flemish painter, son of Alexander van Bredael (d. 1720), also an artist, was born in Antwerp. He imitated the style of Wouwerman and Breughel with much dexterity. He visited England, where he was well employed. There were several other van Bredaels, who won honour as artists—notably PIETER (1622-1719), Alexander's father, and JOZER (1688-1739). They were formerly known as "Breda," but this apparently is incorrect, though it occurs as a signature on a picture by Jan Frans in the Amsterdam gallery.

**BREDERODE, HENRY**, VISCOUNT OF (1531-1568), a descendant of the ancient counts of Holland, was born at Brussels in Dec. 1531, and died at Recklinghausen on Feb. 15, 1568. In 1566 he was one of the founders of the confederacy of nobles who bound themselves to maintain the rights and liberties of the Netherlands and to resist the expected introduction of the Inquisition by signing a document known as "the compromise." This document is believed to have been the work of Sante-Aldegonde, with the assistance of Louis of Nassau and Brederode. Brederode was gay and popular, reckless and generous, and one of the principal leaders of the movement. On April 5 of that year 250 confederates assembled at the Hôtel Culemburg and marched to the palace, led by Louis and Brederode, to present to the regent, Margaret of Parma, a petition setting forth their grievances, called "the request." Refusing, in the following August, to take an oath of loyalty demanded by Margaret of Parma, Brederode made unsuccessful attempts to raise an army at Antwerp and Amsterdam; in April 1567 he fled to Emden, where, on hearing of the appointment of the Duke of Alva, he signed a second compromise with seven other exiles. After his death in 1568, Alva passed a sentence of banishment and confiscation on him.

See M. C. Van den Hall, *Heinrich von Brederode* (1845).

**BREDOW**, a shipbuilding district in the Prussian province of Pomerania, lying immediately north of Stettin (*q.v.*), with which it is incorporated.

**BREECH**, a covering for the lower part of the body and legs. The word in its proper meaning is used in the plural, and is confined to a garment reaching to the knees only. The meaning of "the hinder part of the body" is later than, and derived from, its first meaning; this sense appears in the "breech" of a gun. The word is also found in "breeches buoy," a sling life-saving apparatus, consisting of a support of canvas breeches. The "Breeches Bible," a name for the Geneva Bible of 1560, is so called because "breeches" is used for the aprons of fig-leaves made by Adam and Eve. On the stage the phrase a "breeches" part is used when a woman plays in male costume. "Breeching" is a strap passed round the breech of a harnessed horse and joined to the shafts to allow a vehicle to be backed. In military science the word is used to denote the hinder part of a firearm, containing the projectile and propellant. Up till the middle of the 19th century these had to be inserted from the muzzle of the weapon; loading by the breech is universal to-day for guns and all other firearms.

**BREEDS AND BREEDING.** A breed of domestic animals or cultivated plants is a group of individuals which exhibit in common a certain combination of hereditary characters. Breeds have had their origin in the unconscious or accidental selection by man of wild stocks that tolerated the vicinity of man and were useful or attractive to him. Following upon this domestication came the recognition by the pastoralist and husbandman that related individuals maintained under exactly similar conditions differed among themselves, that these variations commonly bred true, and that improvements in husbandry induced a fuller expression of usefulness or attractiveness. The breeder has never possessed the power of invoking the appearance of a new hereditary character, but by guiding the formation of different groupings of these hereditary characters as they presented themselves, he first made the unimproved local breeds of stock and later, as the standards of perfection became more precisely defined and the art of breeding developed, the modern breeds, which differ from local breeds in that inborn dissimilarity among the individuals comprising them is much rarer and less pronounced.

Modern improved breeds are commonly classified as "fancy" and "utility." A fancy breed is one in which the characterization of the ideal type is not directly concerned with economic values, but is one that is attractive. Since the aim of the breeder is to produce individuals that shall win prizes in competitive exhibitions, the standard of the ideal type can be rarely attained, much importance being attached to finer points and shades of characterization. The "fancy" pigeon may or may not be able to fly, but it must have some character, *e.g.*, colour, pattern, size, generally or of local parts, developed to a point that commonly is almost pathological. The "fancy" dog may or may not be useless as a dog, but it must exhibit some hereditary character, *e.g.*, short legs, dished face, hairlessness, developed to its extreme. The utility breeds, on the other hand, are bred for and judged by the productivity and performance of the individuals comprising them. There are milk, beef and draught breeds of cattle, and in addition dual-purpose breeds (milk and beef, or beef and draught) and triple-purpose breeds (milk, beef and draught). There are wool and mutton breeds of sheep, each primarily bred for the production of wool or of mutton, the alternative being regarded more or less as a by-product. There are other breeds of sheep which are dual-purpose breeds. There are the fine-woolled and the long-woolled breeds, each carefully bred and maintained for the production of their own particular kind of fleece in addition to mutton. Of utility rabbits there are "pelt" breeds, bred for their skins, and the Angora bred for its wool. Of utility fowls there are the "egg," the "flesh" and the dual-purpose breeds. From an economic point of view, it would appear that to keep the "all-round" breed on a large scale is less profitable than to keep several single-purpose breeds on a smaller.

Darwin, in his *Variation of Animals and Plants under Domestication* (1868), placed on record a very complete statement of the facts concerning the origin and development of breeds and, moreover, gave to these facts a very rational interpretation. See ANIMAL BREEDING; REPRODUCTION; HEREDITY; MENDELISM; and VARIATION AND SELECTION.

**BIBLIOGRAPHY.**—R. Wallace, *Farm Live Stock of Great Britain*, 5th edn. (1923); J. A. S. Watson and J. A. More, *Agriculture: The Science and Practice of British Farming* (1924). (F. A. E. C.)

**BREEZE.** (1) A current of air less than a "wind," which in turn is less than a "gale." (See BEAUFORT SCALE.) The term is qualified in many different ways, *e.g.*, glacial-breeze—a cold breeze blowing down the course of a glacier; lake-breeze—light wind blowing on to the coast of a lake in sunny weather during the middle of the day; mountain breeze—a mass of air flowing down into the valley during the night; valley breeze—a day breeze blowing up the valleys. The unqualified term is usually applied to the light wind blowing landwards by day, sea-breeze, and the counter wind blowing offshore at night, land-breeze.

(2) In industry breeze is a name given to small cinders and fine coal used in burning bricks. The term is also applied to small clinker and clinker dust. Used as a matrix with Portland cement, breeze is now widely employed to make lintels for building, fixing-bricks, and blocks for building cheap partitions. A breeze for such a purpose should be carefully washed and rendered free from sulphur to prevent disintegration after moulding. The coke-breeze fixing-brick is a very useful product, as it saves much labour in fixing door-frames, skirtings, picture-mouldings, etc. The breeze block will hold nails, and its use therefore makes it unnecessary to plug walls where joinery has to be fixed.

**BREGENZ**, the capital of the Austrian province of Vorarlberg, is situated at the south-east corner of Lake Constance. It has an important nodal position commanding routes from southern Germany to the Upper Rhine valley and the Arlberg as well as communications by water with the other towns on the lake shores. The value of the location is proved by its long and disturbed history, admirably recorded in the collections of the Vorarlberger Landesmuseum. The old town, the *Brigantium* of the Romans, lies on a castle-crowned hill overlooking the modern site. Here, in 1408, the Appenzellers were defeated, while in 1647 during the Thirty Years' War the town was sacked by the Swedes. The rejuvenation of modern times is in great measure due to its possibilities as a port. The principal exports are cattle and the cotton goods manufactured in Vorarlberg, but an important trade in grain and foodstuffs is also carried on; fostered by growth in commerce the town has grown rapidly during the 20th century. Pop. 13,100.

**BREGUET, LOUIS CHARLES** (1880— ), French engineer, a descendant of the famous watchmaker, Abraham Louis Breguet, was born Jan. 2 1880, in Paris. He received his education at the Lycées Condorcet and Carnot, and graduated in science. He was from the outset of his career a prominent member of the engineering firm that bears his family name, and eventually became head engineer of its electric service. The Maison Breguet, which came to the front in French aeronautical construction, provided him with ample ground for research; he published a quantity of reports on aerodynamics, on the energy converted by propellers in motion and on the rise of aircraft from the ground. He studied and equipped in 1909 the first helicopter which was able to rise perpendicularly carrying a passenger.

**BREHON LAWS**, more properly called *Feinechus*, were the ancient laws of Ireland. Brehon (*Breitheamh*) is the Irish word for judge. Regular courts and judges existed in Ireland from prehistoric times.

The extant remains of these laws are ms. transcripts from earlier copies made on vellum from the 8th to the 13th century, now preserved with other Gaelic mss. in Trinity college and the Royal Irish Academy, Dublin, the British Museum, Oxford university, some private collections and several libraries on the continent of Europe. The largest and most important of these documents is the *Senchus Mór*, or "Great Old Law Book." No copy of it now existing is complete. What remains of it occupies the first, second and a portion of the third of the volumes produced by the Brehon Law Commission appointed in 1852.

In the *Annals of the Four Masters* it is said "The age of Christ 438, the tenth year of King Laeghaire (Lairy), the *Senchus Mór* and *Feinechus* of Ireland were purified and written" This entry has some historical corroboration.

The text and earlier commentaries are in the *Bearla Feini*—the most archaic form of the Gaelic language. Many words, phrases and idioms are now obsolete, and so difficult to translate that the official translations are to some extent confessedly conjectural. Frequently only the opening words of the original text remain. Wherever the text is whole, it is curt, elliptical and yet rhythmic. The rigorously authentic character of these laws, relating to, and dealing with, the actual realities of life, and with institutions and a state of society nowhere else revealed to the same extent, the extreme antiquity both of the provisions and of the language, and the meagreness of continental material illustrative of the same things, endow them with exceptional archaic, archaeological and philological interest. No man was allowed to act as judge until he had studied the full law course, which occupied 20 years, and had passed a rigorous public examination. The course of study for judge and law-agent, respectively, is carefully laid down. The Brehon was an arbitrator, umpire and expounder of the law, rather than a judge in the modern acceptation. It appears, without being expressly stated, that the facts of a case were investigated and ascertained by laymen before submission to a Brehon for legal decision. The complainant could select any Brehon he pleased, if there were more than one in his district. Every king or chief of sufficient territory retained an official Brehon, who was provided with free land for his maintenance and acted as registrar or assessor in the king's court. In ordinary cases the Brehon's fee was said to have been one-twelfth of the amount at stake.

Assemblies, national, provincial and local, were a marked characteristic of ancient Irish life. They all, without exception, discharged legal, legislative or administrative functions. Most of the assemblies were annual, some triennial, some lasted only a day or two, others a week and occasionally longer. All originated in pagan funeral or commemorative rites and continued to be held, even in Christian times, in very ancient cemeteries. They were called by different names—*Feis*, *Aenach*, *Dál*, etc. At one assembly held at Uisneach about a century before Christ a uniform law of distraint for the whole of Ireland was adopted. Each provincial kingdom and each *tuath* had assemblies of its own. Very careful provision is made for the preparation of the sites of great assemblies, and the preservation of peace and order at them is sanctioned by the severest penalties of the law.

**The Clan System.**—*Tuath*, *Cinel* and *Clann* were synonyms meaning a small tribe or nation descended from a common ancestor. A king and clan being able, subject to certain limitations, to adopt new members or families, or amalgamate with another clan, the theory of common origin was not rigidly adhered to. Kinship with the clan was an essential qualification for holding any office or property. The rules of kinship largely determined status with its correlative rights and obligations, supplied the place of contract and of laws affecting the ownership, disposition and devolution of property, constituting the clan an organic, self-contained entity, a political, social and mutual insurance co-partnership. The solidarity of the clan was its most important and all-pervading characteristic. According to the traditional view the entire territory occupied by a clan was the common and absolute property of that clan, a portion being set apart for the maintenance of the king. Warriors, statesmen, Brehons, Ollamhs, physicians, poets and even eminent workers in the more important arts, were also rewarded with free lands. Rank, with the accompanying privileges, jurisdiction and responsibility, was based upon a qualification of kinship and of property, held by a family for a specified number of generations, together with certain concurrent conditions; and it could be lost by loss of property, crime, cowardice or other disgraceful conduct. A portion of land called the *Cumhal Senorba* was devoted to the support of widows, orphans and old childless people. According to the later and now very generally accepted view of Prof. Eoin MacNeill there was no communal holding of land by the clan. Clan itself meant little more than a princely family, like, say, the Hohenzollerns in Germany. There was no land, blood or personal name common to the people subject to such a family. Anything in the nature of common holding or redistri-

bution of land was confined to the joint families next to be described.

*Fine* (*finē*), originally meaning family, came in course of time to be applied to a group of kindred families or a joint family group of four generations. Even those who adhere to the traditional view of the clan will admit that in course of time a large and increasing proportion of the good land became limited private property. The area of arable land available for the common use of the clansmen was gradually diminished by these encroachments. The land belonging to the joint family (*finē*) was at intervals liable to redistribution when the joint family broke up. In this distribution men might or might not receive again their former portions. In the latter case compensation was made for unexhausted improvements. This land could not be sold, nor even let except for a season in case of domestic necessity. The holders had no landlord and no rent to pay for this land, and could not be deprived of it except for a crime. They were subject only to public tributes and the ordinary obligations of free men. The unfenced and unappropriated common lands—waste, bog, forest and mountain—all clansmen were free to use promiscuously at will.

**Tenure of Land.**—There was hardly any selling and little letting of land in ancient times. Nobles and other persons holding large areas let to clansmen, not the land, but the grazing of a number of cattle specified by agreement. They also let cattle to a clansman who had none or not enough, and this was the most prevalent practice. There were two distinct methods of letting and hiring—*saer* (=free) and *daer* (=unfree), the conditions being fundamentally different. The conditions of *saer*-tenure were largely settled by the law, were comparatively easy, did not require any security to be given, left the clansman free within the limits of justice to end the connection, left him competent in case of dispute to give evidence against that of the noble, and did not impose any liability on the joint family of the clansmen. By continued use of the same land for some years and discharge of the public obligations in respect of it in addition to the *ciss* or payment as tenant, a clansman became a sub-owner or permanent tenant and could not be evicted. There is no provision in these laws for evicting any one. For the hire of cattle a usual payment was one beast in seven per annum for seven years; after which the cattle that remained became the property of the hirer. *Daer*-tenure, whether of cattle or of the right to graze cattle upon land, was subject to a *ciss-rinisciss* (=wearisome tribute), for the payment of which security had to be given. A man not in the enjoyment of full civil rights, if able to find security could become an unfree clansman. A free clansman by becoming an unfree-clansman lowered his own status and that of his joint family, became incompetent to give evidence against that of a noble, and could not end the connection until the end of the term except by a large payment. The members of his joint family were liable, in the degree of their relationship, to make good out of their own property any default in the payments. Hence this tenure could not be legally entered into by a free clansman without the permission of his joint family. Unfree clansmen were also exposed to casual burdens, like that of lodging and feeding soldiers when in their district. All payments were made in kind. When the particular kind was not specified by the law or by agreement, the payments were made according to convenience in horses, cattle, sheep, pigs, wool, butter, bacon, corn, vegetables, yarn, dye-plants, leather, cloth, articles of use or ornament, etc.

People who did not belong to the clan and were not citizens were in a base condition and incompetent to appear in court in suit or defence except through a freeman. The *Bothach* (=cot-tier) and the *Sen-cléithe* (=old dependant) were people who, though living for successive generations attached to the families of nobles, did not belong to the clan and had no rights of citizenship. *Fuidhirs*, or manual labourers without property, were the lowest section of the population. Some were born in this condition, some clansmen were depressed into it by crime, consequences of war or other misfortune; and strangers of a low class coming into the territory found their level in it. The *fuidhirs* also were

divided into free and unfree; the former being free by industry and thrift to acquire some property, after which five of them could club together to acquire rights corresponding to those of one freeman. The unfree *fuidhirs* were tramps, fugitives, captives, etc.

Fosterage, the custom of sending children to be reared and educated in the families of fellow-clansmen, was prevalent among the wealthy classes. A child in fosterage was reared and educated suitably for the position it was destined to fill in life. There was fosterage for affection, for payment and for a literary education. Fosterage began when the child was a year old and ended when the marriageable age was reached, unless previously terminated by death or crime. Every fostered person was under an obligation to provide, if necessary, for the old age of foster parents. The affection arising from this relationship was usually greater, and was regarded as more sacred than that of blood relationship.

**Law of Contract.**—The solidarity of clan and joint family in their respective spheres, the provisions of the system, the simple rural life, and the prevalence of barter and payments in kind, left comparatively little occasion for contracts between individuals. Consequently the rules relating to contract are not very numerous. They are, however, sufficiently solemn. No contract affecting land was valid unless made with the consent of the joint family. Contracts relating to other kinds of property are more numerous. When important or involving a considerable amount, they had to be made in the presence of a noble or magistrate. The parties to a contract should be free citizens, of full age, sound mind, free to contract and under no legal disability. "The world would be in a state of confusion if express contracts were not binding." From the repeated correlative dicta that "nothing is due without deserving," and that a thing done "for God's sake," i.e., gratis, imposed little obligation, it is clear that the importance of valuable consideration was fully recognized. So also was the importance of time. "To be asleep avails no one"; "Sloth takes away a man's welfare." Contracts made by the following persons were invalid: (1) a servant without his master's authority; (2) a monk without authority from his abbot or manager of temporalities; (3) a son subject to his father without the father's authority; (4) an infant, lunatic, or "one who had not the full vigilance of reason"; (5) a wife in relation to her husband's property without his authority. She was free to hold and deal with property of her own and bind it by contract. If a son living with his father entered into a contract with his father's knowledge, the father was held to have ratified the contract unless he promptly repudiated it. "One is held to adopt what he does not repudiate after knowledge, having the power." Contract of sale or barter with warranty could be dissolved for fraud, provided action was taken within a limited time after the fraud had become known. Treaties and occasional very important contracts were made "blood covenants" and inviolable by drawing a drop of blood from the little finger of each of the contracting parties, blending this with water, and both drinking the mixture out of the same cup. The forms of legal evidence were pledges, documents, witnesses and oaths. In cases of special importance the pledges were human beings, "hostage sureties." These were treated as in their own homes according to the rank to which they belonged, and were discharged on the performance of the contract. If the contract was broken they became prisoners and might be fettered or made to work as slaves until the obligation was satisfied. Authentic documents were considered good evidence. A witness was in all cases important, and in some essential to the validity of a contract. His status affected the force of the contract as well as the value of his evidence; and the laws appear to imply that by becoming a witness, a man incurred liabilities as a surety. The pre-Christian oath might be by one or more of the elements, powers or phenomena of nature, as the sun, moon, water, night, day, sea, land. The Christian oath might be on a copy of the Gospels, a saint's crozier, relic or other holy thing.

**Criminal Laws.**—These laws recognized crime, but in the same calm and deliberate way in which they recognized contract

and other things seriously affecting the people. Although we find in the poems of Dubhthach, written in the 5th century and prefixed to the *Senchus Mór*, the sentences "Let every one die who kills a human being," and "Every living person that inflicts death shall suffer death," capital punishment did not prevail in Ireland before or after. The laws uniformly discountenanced revenge, retaliation, the punishment of one crime by another, and permitted capital punishment only in the last resort, and in ultimate default of every other form of redress. They contain elaborate provision for dealing with crime, but the standpoint from which it is regarded and treated is essentially different from ours. The State, for all its elaborate structure, did not assume jurisdiction in relation to any crimes except political ones, such as treason or the disturbance of a large assembly. For these it inflicted the severest penalties known to the law—banishment, confiscation of property, death or putting out of eyes. A crime against the person, character or property of an individual or family was regarded as a thing for which reparation should be made, but the individual or family had to seek the reparation by a personal action. This differed from a civil action only in the terms employed and the elements used in calculating the amount of the reparation. The function of a judge in a criminal as in a civil action was to see that the facts, with modifying circumstances, were fully and truly submitted to him, and then by applying the law to these facts to ascertain and declare the amount of compensation that would make a legal adjustment. For this amount the guilty person and in his default his kindred, became legally debtor, and the injured person or family became entitled to recover the amount like a civil debt by distraint. There were no police, sheriffs or public prisons. The decisions of the law were executed by the persons concerned, supported by a highly organized and disciplined public opinion springing from honour and interest and inherent in the solidarity of the clan. Prof. MacNeill, however, contends that the State took a far more active part in enforcing Brehon decisions than that herein described, the king in general acting as judge, subject to professional advice. There is good reason to believe that the system was as effectual in the prevention and punishment of crime and in the redress of wrongs as any other human contrivance has ever been.

In calculating the amount of compensation the most characteristic and important element was *Enechlann* (=honour-price, honour-value), a value attaching to every free person, varying in amount from one cow to 30 cows according to rank. It was the assessed value of *status* or *caput*. It was frequently of consequence in relation to contracts and other clan affairs; but it emerges most clearly in connection with crime. By the commission of crime, breach of contract, or other disgraceful or injurious conduct, *Enechlann* was diminished or destroyed, a *capitis diminutio* occurred, apart from any other punishment. Though existing apart from fine, *Enechlann* was the first element in almost every fine. *Dire* was the commonest word for fine, whether great or small. *Eric* (=reparation, redemption) was the fine for "separating body from soul"; but the term was used in lighter cases also. In capital cases the word sometimes meant *Enechlann*, sometimes *coirp-dire* (=body-fine), but most correctly the sum of these two. It may be taken that, subject to modifying circumstances, a person guilty of homicide had to pay (1) *coirp-dire* for the destruction of life, irrespective of rank; (2) the honour-value of the victim; (3) his own honour-value if the deed was unintentional; and (4) double his own honour-value if committed with malice aforethought. The sum of these was in all cases heavy; heaviest when the parties were wealthy. The amount was recoverable as a debt from the criminal to the extent of his property, and in his default from the members of his joint family in sums determined by the degree of relationship; and it was distributable among the members of the joint family of a murdered person in the same proportions, like a distribution among the next of kin. The joint family of a murderer could free themselves from liability by giving up the murderer and his goods, or if he escaped, by giving up any goods he had left, depriving him of clanship and lodging a pledge against his future mis-

deeds. In these circumstances the law held the criminal's life forfeit, and he might be slain or taken as a prisoner or slave. He could escape only by becoming an unfree labourer in some distant territory. When the effect of a crime did not go beyond an individual, if that individual's joint family did not make good their claim while the criminal lived, it lapsed on his death. "The crime dies with the criminal." If an unknown stranger or person without property caught red-handed in the commission of a crime refused to submit to arrest, it was lawful to maim or slay him according to the magnitude of the attempted crime. "A person who came to inflict a wound on the body may be safely killed when unknown and without a name, and when there is no power to arrest him at the time of committing the trespass." For crimes against property the usual penalty, as in breach of contract, was generic restitution, the quantity, subject to modifying circumstances, being twice the amount taken or destroyed.

**Law of Distress.**—Distress or seizure of property being the universal mode of obtaining satisfaction, whether for crime, breach of contract, non-payment of debt, or any other cause, the law of distress came into operation as the solvent of almost every dispute. Hence it is the most extensive and important branch, if not more than a branch, of these ancient laws. There was no sale, because sale for money was little known. The property in the thing seized, to the amount of the debt and expenses, became legally transferred from the debtor to the creditor, not all at once but in stages fixed by law. A creditor was not at liberty to seize household goods, farming utensils, or any goods the loss of which would prevent the debtor recovering from embarrassment, so long as there was other property which could be seized. A seizure could be made only between sunrise and sunset. "If a man who is sued evades justice, knowing the debt to be due of him, double the debt is payable by him and a fine of five *seids*." When a large debt was clearly due, and there was no property to seize, the debtor himself could be seized and compelled to work as a prisoner or slave until the debt was paid.

When a defendant was of rank superior to that of the plaintiff, distress had to be preceded by *troscað* (=fasting). This is a legal process unknown elsewhere except in parts of India. The plaintiff having made his demand and waited a certain time without result, went and sat without food before the door of the defendant. To refuse to submit to fasting was considered indelibly disgraceful, and was one of the things which legally degraded a man by reducing or destroying his honour-value. The law said, "he who does not give a pledge to fasting is an evader of all; he who disregards all things shall not be paid by God or man." If a plaintiff having duly fasted did not receive within a certain time the satisfaction of his claim, he was entitled to distrain as in the case of an ordinary defendant, and to seize double the amount that would have satisfied him in the first instance. If a person fasting in accordance with law died during or in consequence of the fast, the person fasted upon was held guilty of murder. Fasting could be stopped by paying the debt, giving a pledge, or submitting to the decision of a Brehon. A creditor fasting after a reasonable offer of settlement had been made to him forfeited his claim. "He who fasts notwithstanding the offer of what should be accorded to him, forfeits his legal right."

**BIBLIOGRAPHY.**—Pending the work of a second Brehon Law Commission, the Laws are best studied in the six imperfect volumes (*Ancient Laws of Ireland*, 1865-1901) produced by the first Commission (ignoring their long and worthless introductions), together with Dr. Whitley Stokes's *Criticism* (1903) of Atkinson's *Glossary* (1901). The following are important references (kindly supplied by Dr. Whitley Stokes) for detailed research:—R. Dareste, *Études d'histoire de droit*, pp. 356-381 (1889); Arbois de Jubainville and Paul Collinet, *Études sur le droit celtique* (2 vols., 1895); Joyce, *Social History of Ancient Ireland*, vol. i. pp. 168-214 (2 vols., 1903); *Zeitschrift für celtische Philologie*, iv. 221 (see also vol. 14, p. 1 and vol. 15); the Copenhagen fragments of the Laws (Halle, 1903); important letters in *The Academy*, Nos. 699, 700, 701, 702, 703, 704, 706, 707 (substantially covered by Stokes's *Criticism*); *Revue Celtique*, xxv. 344; *Eriu* i. 209-15 (collation by Kuno Meyer of the Law tract Crith Gablach). Maine's *Early Hist. of Institutions* (1875) and *Early Law and Custom*, pp. 162, 180 (1883); Hearn's *Aryan Household* (1879) and MacLennan's *Studies in Ancient History*, pp. 453-507 (1876), contain interesting general reference, but the writers were not themselves original

students of the laws. L. Ginnell's *Brehon Laws* (1894) may also be consulted. See also A. Ua Clerigh, *History of Ireland to the Coming of Henry II.*, chaps. 14 and 15 (1908); E. MacNeill, *Phases of Irish History*, chaps. 10 and 12 (1919); S. Bryant, *Liberty, Order and Law under Native Irish Rule* (1923); R. Thurneysen, *Cóic Conara Fugill (Die fünf Wege zum Urteil)* (1926); and the article CELT, sections *Language and Literature*. (M. J. R.; A. E. C.)

**BREISACH**, a town of Germany, in the republic of Baden, standing on a basalt rock 250ft. above the Rhine, 10m. W. of Freiburg. Pop. (1925), 3,131. Breisach (*Brisiacum*), formerly an imperial city and until the 18th century one of the chief fortresses of the empire, is of great antiquity. A stronghold of the Sequani, it was captured in the time of Julius Caesar by Ariovistus and became known as the *Mons Brisiacus*. Fortified by the emperor Valentinian in 369 to defend the Rhine against the Germans, it remained throughout the middle ages one of the chief bulwarks of Germany and was called the "cushion and key (*Kissen und Schlüssel*) of the German empire." It gave its name to the district Breisgau. In 939 it was taken by the emperor Otto I., and remained the exclusive possession of the emperors for two centuries. In 1254 and 1262 the bishops of Basle obtained full control over it, but in 1275 it was made an imperial city by King Rudolph I., and the Habsburgs possessed it from the 14th century. In the Thirty Years' War Breisach successfully resisted the Swedes, but it was forced to capitulate to the Protestants after a memorable siege in 1638. The French held it from 1648, and it was several times besieged by them after its restoration to Austria in 1697. By the peace of Pressburg (1805) it was finally incorporated with Baden, and the fortifications were razed. Two mediaeval gates, however, remain. It has a fine minster, partly Romanesque, partly Gothic, dating from the 10th to the 15th centuries; one western tower is 13th century Gothic, the other Romanesque. The interior is remarkable for the wood-carving of the high altar, and for tombs and pictures. There is little industry, but a considerable trade is done in wines and other agricultural produce. On the opposite bank of the Rhine, here crossed by a railway bridge, lies the little town of Neubreisach, built as a fortress by Louis XIV.

**BREISGAU**, a district of Germany, in the free state of Baden. It extends along the right bank of the Rhine from Basle to Kehl, and includes the principal peaks of the southern Black Forest and the Freiburg valley. The Breisgau, at one time a district or *gau* (Lat. *pagus*) of the Frankish empire, was ruled during the middle ages by hereditary counts. Of these the earliest recorded is Birtilo (962-995), ancestor of the counts and dukes of Zähringen. On the death of Berchthold V. of Zähringen in 1218, his co-heiresses brought parts of the Breisgau to the counts of Urach and Kyburg, while part went to the margraves of Baden. The male Urach line becoming extinct in 1457, an heiress carried to the house of Baden what had not been alienated to the Habsburgs. In the struggle between France and Austria from the 17th century onwards the Breisgau frequently changed masters. In 1801 Austria was forced to cede it to Ercole III., duke of Modena, in compensation for the duchy of which Napoleon had deprived him. His successor Ferdinand took the title of duke of Modena-Breisgau, but on his death in 1805 the Breisgau was divided between Baden and Württemberg. The latter ceded its portion to Baden in 1810.

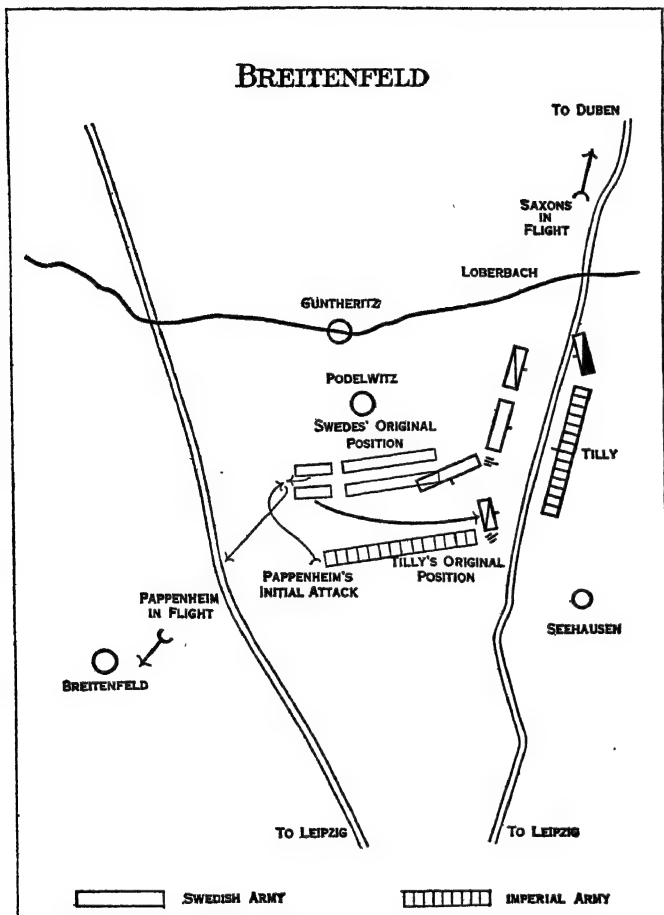

See Stokvis, *Manuel d'histoire*, etc. (Leyden, 1890-93).

**BREISLAK, SCIPIONE** (1748-1826), Italian geologist of German parentage, was born at Rome, where he was a professor in the college of Ragusa, and then in the Collegio Nazareno. The king of Naples invited him to inspect the mines and similar works in that kingdom, and appointed him professor of mineralogy to the royal artillery. The vast works for the refining of sulphur in the volcanic district of Solfatara were erected under his direction. His *Topografia fisica della Campania* (1798) contains the results of much accurate observation. He was an exile in Paris from 1799 until 1802, when he was appointed inspector of the saltpetre and powder manufactories near Milan. The mineral Breislakite was named after him.

**BREITENFELD**, a village in Saxony, 5½m. N.N.W. of Leipzig, noted in military history. The first battle of Breitenfeld was

fought on Sept. 17, 1631, between the allied Swedish and Saxon armies under Gustavus Adolphus and the imperial forces under Count Tilly (see THIRTY YEARS' WAR). The latter's invasion of Saxony had driven the Elector to abandon his long-sustained neutrality, and his urgent appeal for aid had brought Gustavus from the Elbe. On the plain between, but in advance of the villages of Seehausen and Breitenfeld, on the crest of a gentle slope, Tilly drew up his army in order of battle, covering a front of about two and a half miles. Controversy has raged on many

PLAN OF THE BATTLE OF BREITENFELD, 1631, SHOWING THE SUCCESSIVE DISPOSITIONS OF THE ALLIED SWEDISH AND SAXON TROOPS AND THE IMPERIAL FORCES

When the Saxons were forced to retire, Tilly moved his infantry (Imperial forces) to a position to attack the exposed Swedish left flank. A brilliant counter manoeuvre was executed by Gustavus, cutting Tilly off from his communications at Leipzig and separating him from his artillery. The result was the complete defeat of the imperial army

of the details, not least Tilly's original dispositions, although it would seem most probable that it was originally formed in two, with a reserve in the rear, rather to the right centre behind the guns and on a slight elevation. When, however, the rout of the Saxons gave him the opportunity to move his infantry to the right to attack the exposed flank of the Swedes, he probably pushed the "battalia" of his second line forward into the intervals of the first line for the purpose of this oblique move and attack. The infantry formed 13 or 17 solid squares of from 1,500 to 2,000 men apiece. Tilly's cavalry were on the two wings, as was customary, Pappenheim on the left, Fürstenburg and Isolani on the right, a total of about 10,000, making altogether an army of about 35,000—rather less than the combined forces of the Swedes and Saxons, but, after the early rout of the latter, far superior to the Swedes alone. Only in guns had Tilly a marked inferiority.

Early in the morning of Sept. 17, 1631, the allied armies, in two columns, Swedes on the right and Saxons on the left, crossed the Loberbach, a marshy stream running across their front. The formality of the time is well shown by the failure to fall on

Gustavus during this crossing. Only Pappenheim with some 2,000 cavalry went forward to hinder the advance, but the Scots of the vanguard, supported by dragoons, drove him back. Gustavus formed his army in two lines and a reserve. On his left was drawn up the Saxon army. By noon the armies were in position and the battle opened with an artillery duel, in which Torstensson's guns fired three shots to the imperialists' one. This continued for over two hours, when the fiery Pappenheim, without awaiting orders, moved his cavalry to the left to outflank the Swedish right, and then swinging round struck at the Swedish flank. The manoeuvring power and flexible formation of the Swedes enabled Gustavus to wheel up his second line cavalry at right angles to the first and so form a defensive flank, which, strengthened by musketeers, proved a rampart on which Pappenheim's cuirassiers broke themselves to pieces.

After seven vain assaults the imperial cavalry fell back discouraged, and, followed up sharply by the Swedes, were driven in flight from the field. Meanwhile critical events had been taking place on the other wing. The imperial cavalry, under Fürstenburg, had fallen on the Saxons, and in a short half hour almost the whole army, infantry and cavalry alike, were in disorderly flight—thus laying bare the flank of the Swedes.

Inspired by the rout of the Saxons, Tilly now ordered his centre to move to the right and follow in the wake of Fürstenburg, and by an oblique march brought his heavy infantry "battles" into line on the flank of the Swedes. It was a manoeuvre in which we can perhaps find the germ of Frederick the Great's famous "oblique order" of attack. But he was meeting an alert, not a supine enemy, and one, moreover, whose flexible formations enabled him to manoeuvre more quickly than Tilly's unwieldy squares. Horn, commanding the Swedish cavalry on this wing, swung back his first line and wheeled up his second to oppose a new front to this attack in flank, while Gustavus hurried infantry from his second line to reinforce him and prolong the line. With the issue still uncertain, there came a decisive stroke; with his right wing now secure, since Pappenheim's flight, Gustavus himself, taking a large part of his right wing cavalry, swept round and over Tilly's original position, where his guns remained, cutting him off from Leipzig. The captured guns were turned to enfilade Tilly's new left flank, while Torstensson with the Swedish artillery pounded his front, and Gustavus made a general wheel with his centre and right to attack the imperial left. Assailed in front and partly in flank, with their close-packed ranks torn by a double weight of artillery fire, the rigid and immobile imperial squares could but offer a hopeless resistance. The end was inevitable, and though their stand was magnificent, nightfall saw the scattered remnants in headlong flight. The long invincible imperial army, under whose iron heel all Germany had lain prone in ruin or terror, was not merely defeated but destroyed for all practical purposes of resistance. Apart from an actual loss of about 12,000, the fugitives were so dispersed that Tilly on his retreat could rally but 600 and Pappenheim only another 1,400.

The victory struck terror into the hearts of the empire—Vienna was said to be "dumb with fright," Bohemian forests were laid low to block the road, the walls of cities hundreds of miles from the battlefield were kept manned. For the moment the emperor could raise no effective forces to oppose Gustavus's advance. At a council of war the Elector of Saxony and Count Horn, besides many other officers, advocated an immediate advance on the imperial capital. More notable still, Oxenstierna the prudent, though not present at Breitenfeld, was strongly in favour of this plan. But Gustavus decided otherwise—to move into south-west Germany, giving as his reasons that he did not wish to lose sight of Tilly, and that he wished to make use of the resources of the Catholic dioceses there for the maintenance of his army, so allowing the Protestants of North Germany a chance to recuperate.

Whether his decision was guided by the highest wisdom is a moot point. Those who support it point to the value of consolidating his position, of rallying new friends to his standard, and simultaneously gaining a grip on the territories of the Catholic League—thus he could organize a fresh centre of Protestant power

before attempting greater schemes. On the other hand, we need to remember that this move on the Rhine earned him the distrust of France, his ally, and that never again did the imperial power appear so shaken, or its seat so defenceless, as on the morrow of Breitenfeld.

The village of Breitenfeld also gives its name to another great battle in the Thirty Years' War (Nov. 2, 1642), in which the Swedes under Torstensson defeated the imperialists under the archduke Leopold and Prince Piccolomini, who were seeking to relieve Leipzig. The Swedish cavalry delivered the decisive stroke of the day on this occasion also. (B. H. L. H.)

**BREITNER, GEORGE HENDRIK** (1857-1923), Dutch painter, was born Sept. 12 1857, at Rotterdam. He began to study painting at The Hague, and was a pupil of William Maris. His early work showed the influence of Rochussen, who was the first to discover Breitner's great talent. In later years he was strongly influenced by Jacob Maris's colouring, but afterwards became an independent impressionist. The subjects of his pictures were chosen from old parts of Amsterdam, from popular life in the town or from the vigorous movements of manoeuvring cavalry and artillery. He died at Amsterdam June 5 1923.

**BREMEN**, a Free State of Germany, with constitution adopted on May 15, 1920. Area, 99sq.m.; pop. (1925) 338,846. It falls into three distinct parts: (1) the largest portion, with the city of Bremen, lying chiefly on the right bank of the lower Weser, surrounded by the Prussian province of Hanover and the republic of Oldenburg, and consisting in the main of lowland country intersected by canals and dikes; (2) the town and district of Vegesack, lying immediately north of the main portion, on the right bank of the river; (3) the port of Bremerhaven, 46m. down the Weser, at its mouth. Of the whole territory about one-half is meadow and grazing land, one-quarter under tillage, and the remainder woodland, sandy wastes, river surface or urban agglomerations. Market gardening, the rearing of cattle, for which the district is widely famed, and fishing form the chief rural occupations. About 87% of the inhabitants are Protestants, and 7% Roman Catholics. The highest power in the State resides in the House of Burgesses (*Bürgerschaft*), which consists of 120 representatives, chosen by all citizens of the State. The Senate, an executive body of 14 members, is elected by the *Bürgerschaft*. Two *Bürgermeister* preside over its deliberations. Bremen was formerly a free port, but from October 1888, the State, with the exception of two small free districts in Bremen and Bremerhaven, joined the German customs union. The State has two *Amtsgerichte* (courts of first instance) as Bremen and Bremerhaven respectively, and a superior court (*Landgericht*) at Bremen, whence appeals lie to the *Oberlandesgericht* for the Hanseatic towns at Hamburg. The 31m. of railway are owned and worked by the State.

**BREMEN**, city and seaport of Germany, capital of the Free State of Bremen, and one of the Hanseatic towns, occupying a sandy plain on both banks of the Weser, 46m. from the North sea. Pop. (1925) 294,966. The city consists of four quarters: the old town (*Altstadt*) and its suburban extensions (*Vorstadt*) being on the right bank of the river, and the new town (*Neustadt*) with its southern suburb (*Südevorstadt*) on the left bank. The river is crossed by three bridges, the old, the new (1872-1875), and the railway bridge. The former ramparts are promenades. Two new communes and parts of two others were added in 1921.

The romantic old town, with its winding streets flanked by massive gabled houses, dates from Hanseatic days. The fine town hall (*Rathaus*) on the market square dates from the 15th century and has a handsome Renaissance façade. Before it stands a statue of Roland, the emblem of civic power. The *Rathaus*, as well as the cathedral and bourse, was damaged in the Spartacist disturbances of 1919. Within, there is a handsome gallery of paintings, and in an upper hall a model of an old Hanseatic frigate, with the device *Navigare necesse est, vivere non est necesse*, hangs from the ceiling. The cathedral of St. Peter (12th century) on the site of Charlemagne's wooden church, has a famous lead roof. The churches of St. Ansgarius, of Our Lady and of St. Stephen date from the 12th and 13th centuries. Other interesting build-

ings are the Schütting, or merchants' hall, originally built in 1619 for the cloth-traders' gild, and the *Stadthaus*, the former archbishop's palace. There are numerous handsome modern buildings. A beautiful park occupies the *Bürgerweide* (meadows) to the north-east of the city. Bremen, with its predominance of one-family houses, contrasts with most German towns where the flat system is widespread.

The industries are those typical of a modern port and include shipbuilding, milling of oils and grains, jute-spinning, rope-making and the production of tobacco, chemicals, sugar and rice; there are extensive shipbuilding yards. Ships of 25ft. draught are able to reach the port, and the waterway is kept open in winter by ice-breakers. The length of docks approximates 30,000 metres. Total water area (1927), 126 acres. Trade is predominantly transit; excellent railway communications are maintained with the chief industrial districts of Germany. Electric tramways and local steamboats serve the immediate neighbourhood.

The chief imports are coal, grain, cotton, wood, iron ore, rice, oil-seeds, mineral oils, wool, tobacco, cottonseed, meal, asphalt, rice offal, copper, coffee, jute, wine, herrings, etc. The exports include woollen goods, glass, iron and iron wares, machinery, wire, cement and mineral salts. Bremen is specially important as the importer of raw products from America and inter-tropical lands; vast quantities of tobacco and rice are handled. For international trade it ranks as the chief port of Germany, after Hamburg: 3,603 vessels entered in 1925, with aggregate tonnage of 3,893,299.

## HISTORY

In 787 Bremen was chosen by St. Willehad, whom Charlemagne had established as bishop in the *pagi* of the lower Weser, as his see. In 848 the destruction of Hamburg by the Normans led to the transference of the archiepiscopal see of Hamburg to Bremen. In 965 the Emperor Otto I. granted to Archbishop Adalag "in the place called Bremun" the right to establish a market, and the full administrative, fiscal and judicial powers of a count, no one but the bishop or his *advocatus* being allowed to exercise authority in the city—a privilege frequently confirmed by subsequent emperors. There is no direct evidence of the existence of any communal organization during this period, but it is clear from the vigorous part taken by the burghers in the struggle of the Emperor Frederick with Henry the Lion of Saxony that some such organization very early existed. In the 13th century, however, Bremen was still strictly subordinate to the archbishop and his *Vogt*; the council could issue regulations only with the consent of the former, while in the judicial work of the latter, save in small questions of commercial dishonesty, its sole function was advisory. By the middle of the 14th century this situation was reversed; the elected town council was the supreme legislative power in all criminal and civil causes, and in the court of the *advocatus* two *Ratsmänner* sat as assessors. The victory had been won over the archbishop; but a fresh peril had developed in the course of the 13th century in the growth of a patrician class, which, as in so many other cities, threatened to absorb all power into the hands of an oligarchy. In 1304 the commonalty rose against the patricians and drove them from the city, and in the following year gained a victory over the exiles which was long celebrated by an annual service of thanksgiving. After a century of trouble, in 1433 the old aristocratic constitution was definitively restored. But though in Bremen the efforts of the craftsmen's "arts" to secure a share of power had been held in check, the city government did not, as at Cologne and elsewhere, develop into a close patrician oligarchy. No artificial restraint was placed upon individual enterprise, and the question of the government having been settled, Bremen rapidly developed in wealth and influence.

The Reformation was introduced into Bremen in 1522 by Heinrich von Zütphen. Archbishop Christopher of Brunswick-Wolfenbüttel (1487-1558), a brutal libertine, hated for his lusts and avarice, looked on the reforming movement as a revolt against himself. He succeeded in getting the reformer burned; but found himself involved in a life and death struggle with the city. Archbishop Christopher was succeeded in 1558 by his

brother Georg, bishop of Minden (d. 1566), who is reckoned as the last Roman Catholic archbishop of Bremen. His successor Henry III. (1550–85), was a Lutheran and married. Protestantism was not, however, definitively proclaimed as the state religion in Bremen until 1618. The last archbishop, Frederick II. (of Denmark), was deposed by the Swedes in 1644. In 1646 Bremen received the privileges of a free imperial city from the Emperor Ferdinand III. The Swedes, during their occupation of Bremen, refused to consent to this: but in 1720, when the elector of Hanover (George I. of Great Britain) acquired the archbishopric, he recognized Bremen as a free city. In 1806 it was taken by the French, and subsequently annexed by Napoleon to his empire. Restored to independence by the congress of Vienna in 1815, it subsequently became a member of the German Confederation, and in 1867 joined the North German Confederation, with which, in 1871, it was merged in the German empire.

During the political and social upheaval in Germany at the conclusion of the World War, a Workers' and Soldiers' Council was set up in Bremen and, on Nov. 15, 1918, the red flag was hoisted at the Rathaus. Comparative order had been maintained but, on Jan. 10, 1919, the workers united in a protest against the existing government and in a demand for a Communist Republic. After many days of unrest, severe street fighting took place on Feb. 4 and the following days, and order was not completely restored until Feb. 9, when the town and its outskirts were occupied by government troops.

See Buchenau, *Die freie Hansestadt Bremen* (3rd ed., Bremen, 1900); *Bremisches Urkundenbuch*, edited by R. Ehmck and W. von Bippen (1863, fol.); W. von Bippen, *Geschichte der Stadt Bremen* (Bremen, 1892–98); F. Donandt, *Versuch einer Geschichte des bremischen Stadt-rechts* (Bremen, 1830); *Bremisches Jahrbuch* (1864–1900); and Karl Hegel, *Städte und Gilden*, vol. ii. p. 461 (Leipzig, 1891); Wilhelm Breves, *Bremen in der deutschen Revolution* (Bremen, 1919).

**BREMER, FREDRIKA** (1801–1865), Swedish novelist, was born at Tuorla, Finland, on Aug. 17, 1801. Her father, a wealthy iron master and merchant, purchased an estate at Årsta, about 20m. from Stockholm. During a tour in central Europe in 1820–21, Miss Bremer became acquainted with Schiller's works, which made a deep impression on her. She had begun to write verses from the age of eight, and in 1828 she published the first volume of her *Teckningar ur hvardagslivet* (1828). The second volume (1831), containing one of her best tales, *Familjen H.*, gave decisive evidence that a real novelist had been found in Sweden. She increased her reputation by *Presidentens döttrar* (1834), *Grannarne* (1837) and others. After her father's death in 1830 she lived for some time in Norway, and in the autumn of 1849 went to America, returning through England. The admirable translations (1846, etc.) of her works by Mary Howitt secured for her a warm and kindly reception. In her later novels *Hertika* (1856) and *Far och dotter* (1858) Fredrika Bremer expounded her views on the emancipation of women. In 1856 she again travelled, and spent five years on the Continent and in Palestine. On her return she settled at Årsta, where she died on Dec. 31, 1865.

See *Life, Letters and Posthumous Works of F. Bremer*, by her sister, Charlotte Bremer, translated by F. Milow (1868). A selection of her works in 6 vols. appeared at Örebro, 1868–72.

**BREMERHAVEN**, a seaport of Germany, in the Free State of Bremen, on the right bank and estuary of the Weser, at the confluence of the Geeste, 38m. N. of the city of Bremen. Pop. (1925) 23,896. It is built on a tract of territory ceded to Bremen by Hanover in 1826, and further increased by treaty with Prussia in 1869. It forms practically a single town with Geestemünde (Prussia), which lies across the Geeste and with which it is connected by a drawbridge. The port was opened in 1830, and its rapid development is due to the enterprise of Johann Smidt (1773–1859), burgomaster of Bremen. Besides an excellent harbour, there are large wet docks, including the Kaiserhafen. This, together with the north portion of the Neuerhafen, constitutes the free harbour. Here are the workshops and dry docks of the North German Lloyd steamship company. The entrance to the port is ice-free nearly all the year round. Shipbuilding and kin-

dred industries are carried on; and there is a fishing industry, with fish-salting and smoking. The chief imports are cotton, tobacco, frozen meat, phosphates, copper and bananas. The exports are of a general character. Vessels that cannot reach Bremen lighten or discharge at Bremerhaven. In 1925, 964 vessels, with net tonnage totalling 1,879,981, entered the port. The town has numerous fine public buildings. It forms an urban agglomeration (population about 100,000) with Wesermünde and its dependent units, Bremerhaven, Fischereihaven, Geestemünde, Lehe, Speckenbüttel and Wuhlsdorf.

**BREMERTON**, a city of Kitsap county, Wash., U.S.A., on an arm of Puget sound, 15m. west-south-west of Seattle. It is on Federal highway 101, and is served by steamers. The population in 1930 was 10,170. The Puget sound navy yard, which employs 4,000 men and has the largest dry docks in the country, is situated here.

**BRENDAN**, BRANDON or BRANDAN (c. 484–578), Irish saint and hero of a legendary voyage in the Atlantic, is said to have been born at Tralee in Kerry in A.D. 484. Mediaeval historians usually call him Brendan of Clonfert, or Brendan son of Finnloga, to distinguish him from his contemporary, St. Brendan of Birr (573). Little is known of the historical Brendan, who died in 578 as abbot of a Benedictine monastery which he had founded twenty years previously at Clonfert in eastern Galway. The story of his voyage across the Atlantic to the "Promised Land of the Saints," afterwards designated "St. Brendan's Island," ranks among the most celebrated of the mediaeval sagas of western Europe. Its traditional date is 565–573. The legend is found, in prose or verse and with many variations, in Latin, French, English, Saxon, Flemish, Irish, Welsh, Breton and Scottish Gaelic. Although it does not occur in the writings of any Arabian geographer, several of its incidents—such as the landing on a whale in mistake for an island—belong also to Arabic folk-literature. Many of Brendan's fabulous adventures seem to be borrowed from the Irish saga of Maelduin or Maeldune, and others belong also to Scandinavian mythology. The oldest extant version of the legend is the 11th century *Navigatio Brendani*.

Only in 1759 was the apparition of St. Brendan's island explained as an effect of mirage.

See C. Wahlund, *Die altfranzösische Prosaübersetzung von Brendans Meerfahrt* (Uppsala, 1900); F. Novati, *La "Navigatio Sancti Brendani" in antico Veneziano* (Bergamo, 1892); G. Schirmer, *Zur Brendanus-Legende*, etc. (Leipzig, 1888); F. Michel, *Les Voyages merveilleux de St. Brendan*, etc. (Paris, 1878); and P. F. Moran, *Acta Sancti Brendani . . . Original Latin Documents connected with the Life of St. Brendan* (Dublin, 1872).

**BRENHAM**, a city in S.E. Texas, U.S.A., 68m. N.W. of Houston; the county seat of Washington county. It is served by the Santa Fe and the Southern Pacific railways. The population in 1920 was 5,066; and it was 5,974 in 1930. It is a shipping point for cotton, grain, poultry, dressed turkeys, and livestock. Its factories include a cotton mill, a cotton compress, a cottonseed oil mill, a broom factory, marble and granite works, and a large hatchery. It was settled about 1844, incorporated in 1866, and chartered as a city in 1873. A commission-manager form of government was adopted in 1920.

**BRENNER PASS**, the lowest (4,495 ft.) and one of the most frequented passes across the Alps in all ages, though the name used in the middle ages was "the route through the valley of Trent." It is the great gate of Italy, and by it most Teutonic invaders reached Italy. Many side passes join this great thoroughfare. It was crossed no fewer than 66 times by various emperors, between 793 and 1402. A carriage road was constructed over it in 1772 and the railway over it in 1864–67. From Innsbruck to the summit of the pass (by rail) is 25 m. The line then descends through the Eisack valley past Bressanone (34 m.) to Bolzano (24 m.). Thence it follows the valley of the Adige to Trent (35 m.) and on to Verona (56½ m.)—in all 174½ m. by rail from Innsbruck to Verona.

**BRENNUS**, I. A leader of the Gauls who invaded Italy in 390 B.C. It should be observed that his name first appears in Livy and is not found in Polybius or Diodorus. It is difficult to disentangle the facts of this invasion from the legends; it seems

clear that Brennus crossed the Apennines, advanced on Rome down the *Via Salaria*, and defeated the Roman army at the Allia, some 12m. from Rome. He then appears to have delayed a day or two on the field, giving time to fortify the Capitol; to have sacked Rome, besieged the Capitol for six months, accepted the offer of the defenders to ransom themselves, and then, probably, departed safely with his booty. Of the rest of the picturesque story, the massacre of the Patricians in their chairs; the night attack on the Capitol, the sacred geese and the exploits of Manlius; the false weights at the paying of the ransom, and the hurling by Brennus of his sword into the scales, with the famous words, "*Vae Victis*," we may believe as much as we please. But the Livian "happy ending," wherein Camillus arrives from the blue at the moment of payment, and wipes out Brennus and his forces together, is really too good to be true.

BIBLIOGRAPHY.—Diod. XIV.: Polyb. II.: Liv. V.

II. Over a hundred years later (279), another Brennus at the head of a band of Gauls invaded Greece. Earlier raiding expeditions from Pannonia had been successful at the expense of Ptolemy Ceraunus in Macedonia. Brennus now advanced through Macedonia towards Greece proper, and was first held up at Thermopylae, and beaten off with great loss. Later, as had happened to Leonidas, the mountain pass was betrayed, but the Greek army was taken off by the Athenian fleet. Brennus, with the advance guard that had gone over the upper pass, pushed on for Delphi with its vast treasure. About 4,000 was the strength of the defending force on the rock, but they had an immensely strong position, and when Brennus collapsed under his wounds the invaders broke and fled, pursued by the Greeks all the way to Thermopylae. Brennus disdained to recover after his defeat, and put an end to his life by draughts of strong wine. Justin says that he was "unable to endure the pain of his wounds," and the humiliation of defeat.

**BRENTANO, KLEMENS** (1778–1842), German poet and novelist, was born at Ehrenbreitstein on Sept. 8, 1778. His sister was the well known Bettina von Arnim, the correspondent of Goethe. He studied at Halle and Jena, where he made the acquaintance of the Schlegels, Hardenberg and Tieck, and afterwards resided at Heidelberg, Vienna and Berlin. In 1818, weary of his somewhat restless and unsettled life, he joined the Roman Catholic Church and withdrew to the monastery of Dülmen, where he lived for some years in strict seclusion. The latter part of his life he spent in Regensburg, Frankfurt and Munich, actively engaged in Catholic propaganda. He died at Aschaffenburg on July 28, 1842. Brentano, whose early writings were published under the pseudonym Maria, belonged to the Heidelberg group of German romantic writers, and his works are marked by excess of fantastic imagery and by abrupt, bizarre modes of expression. But although he possessed no great poetic genius, he occupies an important position in the history of German literature. It was with the publication of *Des Knaben Wunderhorn* (1805–08), of which he was joint editor, that the new character of the Romantic movement showed itself. Instead of the vague profundity typical of the first Romantics, we find here the simplicity of the folksong, a form of lyric which Brentano could imitate most skilfully. A satirical vein was another feature of his work, and appeared in some of his prose writings. Among his first publications were *Satiren und poetische Spiele* (1800), and a romance *Godwi* (1801–02); of his dramas the best are *Ponce de Léon* (1804), *Victoria* (1817) and *Die Gründung Prag's* (1815). On the whole his finest work is the collection of *Romanzen vom Rosenkranz* (published posthumously in 1852); his short stories, and more especially the charming *Geschichte vom braven Kasperl und dem schönen Annerl* (1838), which has been translated into English, are still popular.

Brentano's collected works, edited by his brother Christian, appeared at Frankfurt in 9 vols. (1851–55). The best modern issue is the collected works edited by Carl Schüddekopf (Munich and Leipzig, 1909, etc.). Selections have been edited by J. B. Diel (1873), M. Koch (1892), and J. Dohmke (1893). See J. B. Diel and W. Kreiten, *Klemens Brentano* (1877–78), the introduction to Koch's edition and R. Steig, *A. von Arnim und K. Brentano* (1894).

**BRENTANO, LUDWIG JOSEPH** (called LUJO) (1844–), German economist, was born at Aschaffenburg on Dec. 18, 1844. He received some of his academical education in Dublin, and was professor of political theory in Breslau (1872), and later in Strasbourg, Vienna, Leipzig and Munich. He retired in 1914. He advocated free trade, and in industrial questions, combated the wages fund theory. In 1868 he made a thorough study of trade unionism in England, which resulted in his principal work, *Die Arbeitergilden der Gegenwart* (Leipzig, 1871–72; Eng. trans. by L. T. Smith). The book was assailed by Bamberger and other economists, but is important not only as an authority on modern associations of workmen, but for having given an impetus to the study of the guilds of the middle ages, and the examination of the great stores of neglected information bearing upon the condition of the people in earlier days. Brentano, who received the Nobel Peace Prize in 1927, was a leading pacifist in Germany, and a familiar figure at international peace gatherings.

His other works include *Das Arbeitsverhältnis gemäss dem heutigen Recht* (1877); *Die christlich-soziale Bewegung in England* (1883); *Über das Verhältnis von Arbeitslohn und Arbeitszeit zur Arbeitsleitung* (1893); *Agrarpolitik* (1897); *Die Schrecken des überwiegenden Industriestaats* (1901); *Die Wirtschaftlichen Lehren des christlichen Altertums* (1902); *Die Entwicklung des Wertlehre* (1908); *Die deutsche Getreidezölle* (1911); and also a book on *Malthusianism* (1909). See Neiffer and Palyi, *Lujo Brentano* (1925).

**BRENTFORD**, VISCOUNT: see JOYNSON-HICKS, SIR W. **BRENTFORD**, urban district, Middlesex, England, 10½m. W. of Waterloo terminus, London, by the Southern Railway, at the junction of the river Brent with the Thames. Pop. (1931), including Chiswick, 62,617.

In 1016 Edmund Ironside defeated the Danes at Brentford (Braynford). A toll was granted by Edward I., who gave the town a market, for the construction of a bridge across the river, and in the reign of Henry VI. a hospital of the Nine Orders of Angels was founded near its western side. In 1642 a battle was fought here in which the royalists defeated the parliamentary forces. During the 16th and 17th centuries Brentford was a favourite resort of London citizens; and its inn of the Three Pigeons is frequently alluded to by the dramatists of the period. References in literature point, in most cases, to the town's reputation for excessive dirt. The Grand Junction Canal joins the Brent here and the town's activities include brewing, soap-making, saw-milling, market-gardening, etc.

South of Brentford, towards Isleworth, is Sion House, a mansion founded by Lord Protector Somerset in 1547 and enlarged by Inigo Jones and Robert Adam. The site of Sion or Syon House was previously occupied by a convent of Bridgettine nuns established at Twickenham in 1415 and removed here in 1431.

**BRENTON, SIR JAHLEEL** (1770–1844), British admiral, was born in Rhode Island, U.S.A., on Aug. 22, 1770, the son of Rear-Admiral Jahleel Brenton (1729–1802). He served with great zeal in the peace before the beginning of the war in 1793, but seeing no chance of employment went to serve in the Swedish navy against the Russians. In 1790 he received his commission in the English navy, and until 1799 he served under Earl St. Vincent. As commander of the "Speedy" brig he won much distinction in actions with Spanish gunboats in the Straits of Gibraltar. In 1800 he reached the rank of post-captain, and served as flag-captain to Sir James (afterwards Lord) Saumarez in the action at Algeiras, and in the Straits in 1801. In 1803 he was wrecked on the coast of France, and imprisoned till 1806. His most brilliant action was fought with a flotilla of Franco-Neapolitan vessels outside of Naples in May 1810. He was made a baronet in 1812 and K.C.B. in 1815. Later he became commissioner of the dockyard at Port Mahon, and then at the Cape, and was afterwards lieutenant-governor of Greenwich Hospital till 1840. His brother, CAPTAIN E. P. BRENTON (1774–1839), is best remembered by his writings on naval and military history—*Naval History of Great Britain from the Year 1783 to 1822* (1823) and *The Life and Correspondence of John, Earl of St. Vincent* (1838).

*A Memoir of the Life and Services of Vice-Admiral Sir Jahleel Brenton*, based on his own papers, was published in 1846 by the Rev. Henry Raikes, and reissued by the admiral's son, Sir L. C. L. Brenton, in 1855.

**BRENTWOOD**, urban district, Essex, England; 18m. N.E. of London by the L.N.E. railway (Brentwood and Warley station). Population (1931) 7,209. The neighbouring country is undulating and well wooded. Brentwood was formerly an important posting station on the main road to the eastern counties, which follows the line of the railway to Colchester. The name (*Burntwood*) is supposed to record an original settlement made in a clearing of the forest. The district is largely residential. The old assize house, an Elizabethan structure, remains. A free grammar school was founded in 1557. The county asylum is in the vicinity. There are breweries and brick works. To the south lies Warley Common, with large barracks.

**BRENZ, JOHANN** (1499–1570), Lutheran divine, eldest son of Martin Brenz, was born at Weil, Württemberg, on June 24, 1499. Ordained priest in 1520, he ceased to celebrate mass in 1523. Protected by his patron Duke Ulrich of Württemberg, he was appointed (Jan. 1553) provost of the collegiate church of Stuttgart. He was a strong advocate of Lutheran doctrine, and author of *Syngramma Suevicum* (Oct. 21, 1525), which set forth Luther's doctrine of the Eucharist. He opposed applying the death penalty to anabaptists or other heretics in the *De Haereticis, an sint persequendi* (1554), issued by Sebastian Castellio under the pseudonym of Martinus Bellius. An incomplete edition of his works (largely expository) appeared at Tübingen, 1576–1590. A volume of *Anecdota Brentiana* was edited by Pressel in 1868. He died on Sept. 11, 1570.

See Hartmann and Jäger, *Johann Brenz* (1840–42); Bossert, in *Herzog's Realencyklop.* (1897).

**BRÉQUIGNY, LOUIS GEORGES OUDARD FEUDRIX DE** (1714–1795), French scholar, was born at Gainneville near Havre, on Feb. 22, 1714, and died at Paris on July 3, 1795. After the close of the Seven Years' War he was sent to search in the archives of England for documents bearing upon the history of France, more particularly upon that of the French Provinces which once belonged to England. From this mission (1764–66) Bréquigny brought back copies of about 7,000 documents, which are now in the Bibliothèque Nationale. A useful selection of these documents was published by Jean Jacques Champollion-Figeac, in the collection of *Documents inédits relatifs à l'histoire de France* (2 vols., 1839, 1847). Bréquigny himself drew the material for important studies from the rich mine which he had thus exploited. These were included in the collection of the Académie des Inscriptions. The Revolution interrupted him in his collection of *Mémoires concernant l'histoire, les sciences, les lettres, et les arts des Chinois*, begun in 1776 at the instance of the minister Bertin, when 15 volumes had appeared.

See Champollion-Figeac's preface to the *Lettres des rois et reines; le Comité des travaux historiques*, by X. Charmes, vol. i. *passim*; and the *Catalogue des manuscrits des collections Duchesne et Bréquigny* (in the Bibliothèque Nationale), by René Poupardin (1905).

**BRESCIA** (anc. *Brixia*), episcopal see, Lombardy, Italy, capital of the province of Brescia, at the foot of the Alps, 52m. E. of Milan and 40m. W. of Verona by rail. Pop. (1921) 66,667 (town), 100,168 (commune). The plan is rectangular, with streets at right angles, a Roman peculiarity, though the Roman town occupied only the eastern portion of the later one. The Piazza del Museo marks the site of the forum, and the museum on its north side is in a Corinthian temple with three *cellae*, probably the Capitolium of the city, erected by Vespasian in A.D. 73. It contains a famous bronze statue of Victory, found in 1826. Near it are the remains of the ancient theatre. The castle, at the north-east angle, commands a fine view. The old cathedral (11th–12th century) is a round domed building over a 9th century church, and the Broletto, adjoining the new cathedral (a building of 1604) on the north, is a massive building of the 12th and 13th centuries (the original town hall, now the prefecture and law courts), with a lofty tower. The convent of S. Salvatore, founded by Desiderius, king of Lombardy, has three churches, two of which now contain the fine mediaeval museum. The church of S. Francesco has a Gothic façade and cloisters. The Palazzo del Comune, begun in 1492 and completed by Jacopo Sansovino in 1554–1574, is a magnificent structure, with fine

ornamentation. The church of S. Maria dei Miracoli (1488–1523) has rich details, especially of the reliefs on the façade. Many other churches, and the picture gallery (Galleria Martinengo), contain fine works of the painters of the Brescian school, Alessandro Bonvicino (generally known as Moretto), Girolamo Romanino and Moretto's pupil, Giovanni Battista Moroni. The city has no less than 72 public fountains. Brescia makes iron ware, particularly fire-arms and weapons (one of the government small-arms factories is here), also machinery, woollens, linens and silks, matches, candles, etc. It is the chief centre of the stocking factories of Italy. Mazzano, 8m. E. of Brescia, has stone quarries. Brescia is on the main railway line between Milan and Verona, and has several branch railways and steam tramways.

The ancient Celtic Brixia of the Cenomani submitted to Rome in 225 B.C. Augustus founded a civil colony here in 27 B.C. In 452 it was plundered by Attila, but was the seat of a duchy in the Lombard period. From 1167 it was one of the most active members of the Lombard League. In 1258 it fell into the hands of Eccelino of Verona, and belonged to the Scaligers (della Scala) until 1421, when it came under the Visconti of Milan, and in 1426 under Venice. Early in the 16th century it was one of the wealthiest cities of Lombardy, but has never recovered from its sack by the French under Gaston de Foix in 1512. It belonged to Venice until 1797, then to Austria; it revolted in 1848, and in 1849 was the only Lombard town to rally to Charles Albert, but it was taken after ten days' obstinate street fighting by the Austrians, to be lost in 1859.

See A. Agoletti, *Brescia* (Bergamo, Arti Grafiche, 1909), well illustrated.

**BRESLAU**, a city of Germany, capital of the Prussian province of Lower Silesia, and an episcopal see, situated in a wide and fertile plain on both banks of the navigable Oder, 350m. from its mouth, and 202m. from Berlin on the railway to Vienna. Pop. (1925) 554,996. It is the seventh city of the Republic. The Oder, which here breaks into several arms, divides the city into two unequal halves, crossed by numerous bridges. The larger portion, on the left bank, includes the old or inner town, surrounded by beautiful promenades on the site of the ramparts dismantled after 1813. Outside the ramparts, and across the Oder, lies the new town, with extensive suburbs, containing many handsome streets and spacious squares. In the ancient inner town, with its narrow streets, are several mediaeval buildings of great interest. The cathedral, dedicated to St. John the Baptist, was begun in 1148, completed in the 15th century, and enlarged and restored later. One of its chief treasures is the high altar of beaten silver. The Kreuzkirche (church of the Holy Cross), dating from the 13th and 14th centuries, is an interesting brick building, remarkable for its stained glass and its historical monuments. The Sandkirche, dedicated to Our Lady of the Sand, dates from the 14th century. The Dorotheen, or Minoritenkirche, remarkable for its high-pitched roof, was founded by the emperor Charles IV. in 1351. Of the Evangelical churches the most important is St. Elizabeth (c. 1250), rebuilt in the 14th and 15th centuries, and restored in 1857. The church possesses a celebrated organ, fine stained glass, a magnificent stone pyx (1455) over 52ft. high, and portraits of Luther and Melancthon by Lucas Cranach. The reformation in Silesia was first proclaimed in 1523, in the Gothic church of St. Mary Magdalen (14th century).

The business streets of the city converge upon the Ring, the market square, in which is the 14th–16th century town-hall, a fine Gothic building, containing the Fürstensaal, in which the diets of Silesia were formerly held, while beneath is the famous Schweidnitzer Keller, used since 1355 as a beer and wine house. The university (founded in 1702), a striking Gothic building facing the Oder, was built (1728–1736) as a college by the Jesuits, on the site of the former imperial castle presented to them by the emperor Leopold I., and contains a magnificent hall (Aula Leopoldina), richly ornamented with frescoes. It was greatly augmented by the incorporation of the university of Frankfurt-am-Oder in 1811. The library is specially rich in oriental literature. In 1925 the university had 2,541 students. The faculty of

theology is here mixed (both Protestant and Roman Catholic) as at Bonn, Münster and Tübingen. Breslau has also a famous technical high school, with 896 students. Among other public buildings are the Stadthaus (civic hall), the royal palace, the Government offices (a handsome pile erected in 1887), the provincial House of Assembly, the municipal archives, the courts of law, the Silesian museum of arts and crafts and antiquities, the museum of fine arts and the exchange. Statues and fountains are numerous. It is, however, as a commercial and industrial city that Breslau is most widely known. It is the chief industrial centre of eastern Germany, with iron-founding and manufactures of machinery, linen, clothes, railway-carriages, paper and furniture. Important fairs are held in spring and autumn. Trade is greatly facilitated by its situation close to the extensive coal and iron fields of Upper Silesia, in proximity to the Austrian and Polish frontiers, at the centre of a network of railways and on a deep waterway connecting with the Elbe and the Vistula. Between 1912 and 1917 a new canal, the Breitenbachfahrt, for the use of barges from Upper Silesia, was constructed, linking the Oder with the Alte Oder.

**History.**—Breslau (Lat. *Vratislavia*) is first mentioned by the chronicler Thietmar, bishop of Merseburg, in A.D. 1000, and was made the seat of a bishop in the 11th century. It formed part of Poland until 1163, when it became the capital of an independent duchy. Destroyed by the Mongols in 1241, it soon recovered its former prosperity and received a large influx of German colonists. The bishop obtained the title of a prince of the empire in 1290. When Henry VI., the last duke of Breslau, died in 1335, the city came by purchase to John, king of Bohemia, whose successors retained it until about 1460, giving the growing town many privileges. Disliking the Hussites, Breslau placed itself under the protection of Pope Pius II. in 1463, and a few years afterwards came under the rule of the Hungarian king, Matthias Corvinus. After his death in 1490 it again became subject to Bohemia, passing with the rest of Silesia to the Habsburgs when in 1526 Ferdinand, afterwards emperor, was chosen king of Bohemia. It passed to Prussia in 1741, though held for a short time by the Austrians in 1757, and by the French in 1807 and 1813. The sites of the fortifications, dismantled by the French in 1807 were given to the civic authorities by King Frederick William III., and converted into promenades.

**BRESSANONE** (formerly Brixen), an urban district, province of Bolzano, Italy. Pop. (1921) 4,853 (town); 6,845 (commune); at the confluence of the Isarco and Rienza, with a station on the Brenner railway, 34m. S.E. of that pass, and 24m. N.E. of Bolzano. The aspect of the city is picturesque and very ecclesiastical; it is still the see of a bishop, and contains an 18th-century cathedral, an episcopal palace and seminary, 12 churches and five monasteries. The see was founded at the end of the 8th century (possibly 6th century) at Sabiona on the rocky heights above the town of Chiusa (some way south), but in 992 was transferred to Bressanone which, perhaps a Roman station, had become a royal estate, under the name of *Prichsna*, and in 901 had been given by Louis the Child to the bishop. In 1027 the bishop received from the emperor Conrad II. very extensive temporal powers, which he lost to Austria only in 1803. The town was surrounded in 1030 by walls. In 1525 it was the scene of the first outbreak of the great peasants' revolt. About 5½m. north of it is the great fortress of Franzensfeste, now called Fortezza, built 1833–38, to guard the route over the Brenner and the way eastward up the Val Pusterla.

**BRESSE**, natural region, eastern France, embracing portions of the departments of Ain, Saône-et-Loire and Jura, extending 60m. from the Dombes on the south to the river Doubs on the north, and 20m. from the Saône east to the Jura. Varying from 600 to 800ft. above sea-level, it slopes slightly west. Heaths and coppice alternate with pastures and arable land; pools and marshes are numerous, especially in the north. Its chief rivers are the Veyle, the Reyssouze and the Seille, tributaries of the Saône. The soil is gravelly clay, moderately fertile, and cattle-raising is carried on. The region is especially celebrated for its table poultry. The district belonged in the middle ages to the lords of Bâgé, from whom it passed in 1272 to the house of Savoy. The province,

as such, with Bourg as its capital, was founded in the 15th century. In 1601 it was ceded to France by the Treaty of Lyons, and formed (with the province of Bugey) first a separate government and afterwards part of the government of Burgundy.

**BRESSUIRE**, a town in western France, department of Deux-Sèvres, 48m. N. of Niort. Pop. (1926) 4,785. The town overlooks the Dolo, a tributary of the Argenton. Its history is a series of pillages and burnings, notably in 1214, 1370, 1598 and 1794. The church of Notre-Dame (12th and 15th centuries) has an imposing Renaissance tower, and the castle (built by the lords of Beaumont, vassals of the viscount of Thouars) is in ruins; part of the site is occupied by a modern château. It is an agricultural market-centre and makes woollen goods. Bressuire has a sub-prefect and a tribunal of first instance.

**BREST**, west France, capital of an arrondissement in the department of Finistère, 155m. W.N.W. of Rennes by rail. Pop. (1926) 58,842. It lies north of a magnificent land-locked bay, and occupies the slopes of two hills divided by the river Penfeld, the left bank being regarded as Brest proper, the right as Recouvrance. There are also extensive suburbs to the east. Some hill-sides are so steep that the ascent is made by flights of steps. This is characteristic of many old fishing settlements. Brest was ceded about 1240 by a count of Léon to John I., duke of Brittany. From 1342 to 1397 it was in English hands and the saying was current that "He is not duke of Brittany who is not lord of Brest." By the marriage of Francis I. with Claude, daughter of Anne of Brittany, Brest with Brittany passed to the crown. Richelieu, in 1631, constructed a harbour with wooden wharves, which soon became a station of the French navy. Colbert changed the wooden wharves for masonry and otherwise improved the port, and Vauban's fortifications followed in 1680–88. Fortifications and naval importance have continued to develop. Running round the shore to the south of the town is the Cours d'Ajot promenade. The castle with its donjon and seven towers (12th to 16th century) commands the entrance to the river.

The roadstead consists of a deep indentation formed by coastal subsidence, about 14m. long and averaging 4m. wide, barred by the peninsula of Quélern, leaving the Goulet passage, from 1 to 2m. broad. The outline of the bay is broken by numerous submerged tributary valleys. The naval port, in great part excavated in the rock, extends along both banks of the Penfeld. There are also large naval barracks. The commercial port, separated from the town by the Cours d'Ajot, comprises a tidal port with docks and an outer harbour. The chief imports are wheat, wine, coal, timber, petrol, iron and steel, fertilizers and paper-pulp. Exports: fruit, potatoes, pyrites and pit-props. Besides its sardine and mackerel fisheries, the town has flour-mills, breweries and engineering works, and manufactures of candles, chemicals (from seaweed), boots, shoes and linen. Brest communicates by submarine cable with America and French West Africa.

During the World War Brest became the port of disembarkation for the American Army fighting in France. Troops and material were landed here, and new docks were rapidly constructed and many older ones deepened. Since 1918 Brest has become more and more important as a calling port for trans-Atlantic liners and a leading naval centre. Brest is the seat of a sub-prefect and has tribunals of first instance and of commerce, a chamber of commerce, a board of trade-arbitrators, two naval tribunals and a tribunal of maritime commerce.

**BREST-LITOVSK** (Polish *Brześć-Litewski*), capital of the Polish province of Polesie in 52° 5' N. and 23° 39' E., at the junction of the river Muchowiec with the Bug, and of railways from Warsaw, Kiev, Moscow and East Prussia. Pop. (1867), 22,493; (1921) 29,100, of whom more than one half were Jews. Brest has suffered many calamities in its history. Ravaged by the Mongols in 1241, by the Teutonic knights in the 14th and the Crimean Tatars in the 15th centuries, its population has decreased by over 24,000 during the wars of 1914–18 and 1920. In 1596 the famous council met there which established the United Catholic Church. From 1795 to 1921 it belonged to Russia. The Royal canal (50m. long), constructed in the 18th century, forms a link in the waterways that connect the Vistula and the Dnieper.

**BREST-LITOVSK, BATTLES OF.** Under this heading are related the fortunes of Mackensen's third forward bound in the great offensive of the Central Powers against Russia in 1915. The period covered is from the middle of July to the middle of September. The aim of Mackensen's group of armies, directed between the Bug and Vistula rivers toward Brest-Litovsk—the same direction as that of the first Austrian offensive of the World War—was to force the retirement of the Russians from the Polish salient and, if possible, to cut their line of retreat. His attack was combined with one from the north by Gallwitz's XII. Army against the Narew line. In the upshot, though both attacks were successful, Russian resistance slowed them down sufficiently to enable the forces in the Polish salient to escape.

Mackensen's two previous attacks had carried him from the Dunajec to the San, then, after a pause, to Lemberg (Lwow), which was captured on June 22, and north-east toward the Chelm (Kholm)-Lublin line. Again a short pause was necessary to reorganize his forces and prepare a fresh advance.

**The Armies Employed.**—In the middle of July, when Mackensen resumed his advance, the position of the opposing forces was roughly as follows: The Russian IV. (Ewath), III. (Lesh) and XIII. (Gorbatovski) Armies faced south-west, from the Pilica river near its junction with the Vistula to about Sokal on the Bug (north-east of Lemberg). On the right of this group the II. Army still held the Bzura-Rawa-Ruska positions west of Warsaw; on the left, the VIII., XI. and IX. Armies stretched south along the Upper Bug to Zloczów and thence to the Rumanian border. The Russian losses had been extremely heavy; in the III. Army, for example, five corps mustered between them only 25,000 bayonets. Their morale had naturally suffered.

Mackensen's group comprised, in that order from north-west to south-east, the Austrian IV. Army, the German XI. Army, the new German Army of the Bug (Linsingen), and the Austrian I. Army (Puhallo). The first three were to carry out the main attack between the Bug and the Vistula, while the I. Army was to cover the right and advance towards Włodzimierz Wołyński. Farther south, the Austrian II. Army and German Southern Army were to cover the offensive counter-attack from the east, the same task that the Austrian II. and III. Armies had failed to perform at the beginning of the war. On the extreme right, the VII. Army (Pflanzer-Baltin) was to push forward and clear the southern portion of East Galicia. West of the Vistula Woyrsch's corps of Landwehr was to advance in conjunction with Mackensen's left and if possible cross the river below Dęblin.

**The Fighting Begins.**—Mackensen's attack began on July 15. From the first, progress was slow. The Russians withdrew a few miles, but in no part of the line was any decisive success achieved. On the 18th, for the first time in history, the Prussian Guard met the Russian Guard on the field of battle; honours appear to have been even between them. Meanwhile Woyrsch had overcome the right wing of the Russian IV. Army and reached the Vistula; he crossed on July 28, some 20 m. north of Dęblin. Mackensen attacked again on the 29th and broke through the Russian front half way between Lublin and Chelm; the former place was evacuated on July 31 and the latter on Aug. 1. It had taken Mackensen 17 days to make good the 25 m. to these places.

Gallwitz in the north had also been unable to gain a rapid success and was advancing only slowly. But before the triple threat of the forces of Mackensen, Woyrsch and Gallwitz, the Russians were compelled to evacuate Warsaw and Dęblin, the former on Aug. 4, and the latter on Aug. 5. The Russian left wing (IV., III., XIII. Armies) in front of Mackensen was now executing a wheel to the east, to conform with the retreat of the centre from the salient. Positions had been entrenched in anticipation of this movement. Mackensen made a last effort to break through and intercept the Russian centre between Warsaw and Brest-Litovsk. But his attacks at Lubartow between Aug. 5 and 8 only gained ground slowly, and by Aug. 9 it was obvious that the Russians had escaped from the noose which it had been proposed to draw round their centre. The main portion of Mackensen's group moved north-east towards Brest-Litovsk, exercising a purely frontal pressure on the retreating Russians. The only outflanking

movement now possible in this part of the field was east of the Bug, directed against the rear of Brest-Litovsk. This was attempted by the Austrian I. Army and the Army of the Bug. The former now advanced on Kowel, while the Bug army, which had crossed the river at Włodawa, advanced through the Pinsk Marshes (Polyesie) to cut the Brest-Litovsk-Kobryn-Pinsk railway line.

**The Final Stages.**—The remainder of the story can be quickly told. Under increasing pressure from the Austrian IV. Army and the German XI. Army, the Russians evacuated Brest-Litovsk on Aug. 26. But they held off the Bug army from Kobryn sufficiently long to allow of the safe withdrawal of their forces from Brest-Litovsk. The Austrian I. Army after reaching Kowel sent a cavalry corps across the Pinsk Marshes to join the Bug army, and itself became involved in battle against the south-western group of Russian armies towards Luck (Lutsk) and Równe.

At the end of August Mackensen's force was reduced. The Austrian IV. Army was transferred to the right group, south of the marshes; portions of the XI. Army had already been withdrawn for the Serbian campaign, to which Mackensen himself was now called. What remained of his forces was placed under Linsingen and pursued the Russians as far as Pinsk, where a line was taken up which remained unaltered to the end of the war.

The poverty of the communications had much hampered Mackensen. In his previous drives from the Dunajec and from the San he had depended principally on the effect of his heavy artillery. The lack of roads and railways south of Lublin and Chelm made it difficult to advance his guns and to keep them supplied with ammunition. The Russians, too, had shown all their traditional stubbornness in retreat. In this part of the theatre the Pinsk marshes made a wide enveloping movement impossible, and the direction of Mackensen's advance was inevitable. Ludendorff had foreseen the slowness of advance on this line and had persistently counselled that the main blow should be directed by Kovno and Wilno (Vilna) on Minsk. (See also EASTERN EUROPEAN FRONT CAMPAIGNS and map; DUNAJEC-SAN, BATTLES OF THE; LEMBERG, BATTLE OF; NAREW, BATTLES OF THE.)

**BREST-LITOVSK, TREATIES OF.** Two treaties were signed at Brest-Litovsk early in 1918: on Feb. 9 between the Central Powers and the Ukrainian Republic, and on March 3 between the Central Powers and the Soviet Government of Russia.

On Nov. 20, 1917, following on a resolution passed by the Congress of Russian Soviets in favour of immediate peace, the new Bolshevik Government informed the Central Powers of its readiness to come to terms; on Dec. 1 fighting ceased on the eastern front; and on Dec. 5, as the result of negotiations at Brest-Litovsk, an armistice was arranged for 10 days (extended on Dec. 15 for 30 days more) with a view to negotiating peace.

The first meeting of the peace delegations was held on Dec. 22 in the fortress of Brest-Litovsk, the headquarters of the German Eastern Army. The principal German delegate was Herr v. Kühlmann, the principal Austro-Hungarian Count Czernin; Turkey and Bulgaria were also represented. The chief representative of the Soviet Government, until the arrival of Trotsky on Jan. 7, was Dr. Joffe. The Ukrainian Republic, which claimed independence of Russia, sent a separate delegation, composed wholly of youthful idealists. Its chief spokesmen were Sevryuk, a literary man, and M. Holubowicz; among its members was Prof. Valdemaras, afterwards prime minister of Lithuania.

The Russians at once laid down as a *sine qua non* the principle of "peace without annexations and indemnities, and the recognition of the right of self-determination for all peoples." This was accepted by the Central Powers, but only on condition that it should be agreed to by all the belligerent powers as the basis of a general peace. In the event of their refusing, the Central Powers reserved a free hand in dealing with Russia alone. On Dec. 28 at the close of the preliminary discussions, the Russians were allowed 10 days in which to secure the adhesion of the Entente Powers.

When the conference reopened on Jan. 7 the situation had changed for the worse. The Entente Powers having refused the Russian proposal, it was now a question of concluding a separate peace. The Russians and Ukrainians were now at open war; the latter insisted on negotiating a separate peace and demanded the recognition of their independence—which was conceded by the Central Powers on Jan. 9. On this same day the negotiations with the Russians on territorial questions reached a deadlock. The Germans insisted that Poland, Courland, Lithuania, and parts of Livonia and Esthonia had already determined to attach themselves to the Central Powers; the Russians demanded that a plebiscite should be taken after the withdrawal of the German troops. All efforts at compromise failed, and on Jan. 18 Trotsky left for Petrograd (Leningrad).

The threatened breakdown of the negotiations was less alarming to Germany than to Austria-Hungary, whose internal condition was now desperate. To relieve this situation a separate peace with the Ukraine was proposed, and to this Germany readily assented since the sacrifices involved would be made by Austria-Hungary alone, while Germany would profit by the opening up of the corn supplies of southern Russia. The conditions demanded by the Ukrainians were severe and humiliating, and in order to avoid them Austria-Hungary renewed her efforts to make peace with Russia. But Trotsky, who returned on the 30th, was in no mood for compromise. He could sign a peace, he said, in which Russia would be frankly coerced, but could not declare in Art. I. that there were no annexations and then in Art. II. agree to such annexations. Russia would bow to facts, but would not give "a certificate of morality" to the victors. Thus, after eight days of futile debate, the deadlock continued.

**Treaty with the Ukraine.**—In these circumstances, and in spite of Trotsky's protests, the treaty between the Central Powers and the Ukrainian *Rada* was signed on Feb. 9. Austria-Hungary ceded the district of Cholm to the Ukrainians, undertook to erect the Ruthenian parts of Galicia and the Bukovina into an autonomous crown land, and conceded full rights to the Ruthenian language and culture elsewhere in the monarchy, all of which was a deadly offence to the Poles. In return the Ukrainians undertook to supply the Central Powers with a million tons of breadstuffs annually. If this latter condition were not fulfilled, the whole treaty was to be null and void.

**Breach with Russia.**—Although Trotsky had announced that the treaty with the Ukraine was an unfriendly act which would make peace with Russia impossible, he consented to continue negotiations on a new basis; all "theoretical questions" were to be excluded from the debates, and the territorial settlements were to be made "without qualification." This broke down on the attitude of the German military men, who complained of Bolshevik propaganda in the German army (which Trotsky justified), and rightly suspected Trotsky of playing for time in expectation of the outbreak of revolution everywhere. On the evening of Feb. 10 Trotsky, pressed to explain himself, rose and left the hall, after announcing briefly that Russia would cease hostilities but would not conclude a treaty of peace.

The military, who had throughout hampered the work of Kühlmann and Czernin, were now definitely in the ascendant. On Feb. 18 Germany denounced the armistice and invaded Estonia, her troops reaching the shores of Lake Peipus. On Feb. 19, Petrograd being immediately threatened, Lenin and Trotsky sued for peace, accepting the conditions laid down at Brest-Litovsk. The Germans, however, now delivered an ultimatum embodying fresh demands, including the German occupation of Estonia and Livonia, to which the Russians agreed on Feb. 24. On Feb. 26 the Russian delegation once more appeared at Brest-Litovsk, with Sokolnikov as its chief spokesman.

The proceedings of the conference, which met on March 1, were short. Sokolnikov announced that Russia accepted all the conditions "dictated to her by Germany sword in hand." In vain the Central Powers protested that the ultimatum had contained the results of weeks of discussion. Sokolnikov declared that there could be no question of discussing the treaties "in this atmosphere of force," and that they would sign the drafts submitted to them

"under the eyes of the workmen, soldiers and peasants of all the world, who would judge these treaties." Without further debate the treaty with Russia was signed on March 3.

**The Peace Treaty with Russia.**—This was threefold. The main treaty embodied the territorial cessions mentioned above and, in addition, the cession to Turkey of Kars, Ardahan and Batum. Four annexes regulated the economic relations between the four powers and Russia, on the general basis of reciprocity. Additional treaties regulated the juridical relations between them. Lip-service was done to the principle of "no indemnities," but Russia had to promise to pay 300,000,000 gold roubles as "compensation" for damage done. The treaty was annulled by Germany under the terms of the Armistice of Nov. 11, 1918, and by the Soviet Government two days later. The treaty with the Ukrainian *Rada* was from the first a "scrap of paper." The breadstuffs for which Austria-Hungary had been willing to pay so great a price only materialized in miserably inadequate quantities, under pressure of German arms, and the *Rada* itself was dissolved when the Germans occupied the Ukraine.

**BRETEUIL, LOUIS CHARLES AUGUSTE LE TONNELIER**, BARON DE (1730–1807), French diplomatist, was born at the château of Azay-le-Féron (Indre) on March 17, 1730. He served on embassies to Cologne, St. Petersburg (Leningrad), Stockholm, Vienna, Naples, and again Vienna, until he was recalled in 1783 to become minister of the king's household. A close friend of Marie Antoinette, he presently came into collision with Calonne, who demanded his dismissal in 1787. His influence with the king and queen, especially with the latter, remained unshaken, and on Necker's dismissal on July 11, 1789, Breteuil succeeded him as chief minister. The fall of the Bastille three days later put an end to the new ministry, and Breteuil made his way to Switzerland with the first party of *émigrés*. At Soleure, in Nov. 1790, he received from Louis XVI. exclusive powers to negotiate with the European courts, and soon brought himself into opposition with his old rival Calonne, who held a chief place in their councils. After the failure of the flight to Varennes Breteuil received instructions from Louis XVI., designed to restore amicable relations with the princes. Foreign sovereigns looked on the comte de Provence as the natural representative of his brother and found a pretext for non-interference on Louis's behalf in the contradictory statements of the negotiators. After the execution of Marie Antoinette he retired into private life near Hamburg, returning to France in 1802. He died in Paris on Nov. 2, 1807.

See the memoirs of Bertrand de Molleville (1816) and of the marquis de Bouillé (1884); and E. Daudet, *Coblentz, 1789–1793* (1889), forming part of his *Hist. de l'émigration*.

**BRETHREN IN CHRIST.** After the Reformation there arose in Europe a group known as pietists. A large number of these pietists settled in Lancaster county, Pennsylvania. From this group in Lancaster county a number of permanent church organizations arose—one of them, the Brethren in Christ. At first the Brethren in Christ chose no name, though its members were designated by others as River Brethren as they lived near the Susquehanna river. It was in 1862 that the community chose the name, Brethren in Christ. No honour is given to any one person for the starting of this organization. The Church stands for equality of all communicants. In doctrine it stands for justification by faith, holiness and empowerment, Divine healing, trine immersion, washing the saints' feet, holy kiss, non-resistance, scriptural veiling and the general resurrection of the dead. The officers of the Church are bishops, ministers and deacons. The Church is controlled by a general conference held annually. One delegate is allowed for every 50 members. The members are scattered throughout the United States and Canada. Foreign missionary activities are being carried on in Africa and India;

through city and rural mission stations, through tabernacle meetings and by the placing of young men in neglected sections the Church ministers to about 25,000 people. In 1928 there were about 6,000 communicant members. (A. W. C.)

**BRETHREN, THE CHURCH OF THE:** see GERMAN BAPTIST BRETHREN.

**BRÉTIGNY**, French hamlet (dept. Eure-et-Loir, arrondissement and canton of Chartres, commune of Sours), which gave its name of a treaty concluded there on May 8, 1360, between Edward III. of England and John II. of France. Edward III. obtained, besides Guienne and Gascony, Poitou, Saintonge and Aunis, Agenais, Périgord, Limousin, Quercy, Bigorre, the countship of Gaure, Angoumois, Rouergue, Montreuil-sur-mer, Ponthieu, Calais, Sangatte, Ham and the countship of Guines, John II. had, moreover, to pay 3,000,000 gold crowns for his ransom. On his side the king of England gave up the duchies of Normandy and Touraine, the countships of Anjou and Maine, and the suzerainty of Brittany and of Flanders. The treaty should more properly be called the treaty of Calais, since it was ratified there on Oct. 24, when an important clause in the treaty of Brétigny was omitted.

**BRETON, JULES ADOLPHE AIMÉ LOUIS** (1827-1906), French painter, was born on May 1, 1827, at Courrières, Pas de Calais, France, and died on July 4, 1906. He was sent in 1843 to Ghent, to study under de Vigne, and in 1846 to Baron Wappers at Antwerp. Finally he worked in Paris under Drolling. His first efforts were in historical subjects, "Saint Piat preaching in Gaul"; then, under the influence of the revolution of 1848, he painted "Misery and Despair." In 1853 he exhibited the "Return of the Harvesters" at the Paris Salon, and the "Little Gleaner" at Brussels. Thenceforward he was essentially a painter of rustic life, especially in the province of Artois.

See Jules Breton, *Vie d'un artiste, art et nature* (autobiographical) (Paris, 1891); Marius Vachon, *Jules Breton* (1899).

**BRETON, BRITTON or BRITTAINE, NICHOLAS** (1545?-1626), English poet, was born in the parish of St. Giles-without-Cripplegate. There is no official record of his residence at the university, but the diary of the Rev. Richard Madox tells us that he was at Antwerp in 1583 and was "once of Oriol College." He is supposed to have died shortly after the publication of his last work, *Fantastickes* (1626). Breton found a patron in Mary, countess of Pembroke, and wrote much in her honour until 1601, when she seems to have withdrawn her favour.

His best work is to be found in his pastoral poetry. His *Passionate Shepherd* (1604) is full of sunshine and fresh air, and of unaffected gaiety. The third pastoral in this book—"Who can live in heart so glad As the merrie country lad"—is well known; with some other of Breton's daintiest poems, among them the lullaby, "Come little babe, come silly soule," it is incorporated in A. H. Bullen's *Lyrics from Elizabethan Romances* (1890). His keen observation of country life appears also in his prose idyll, *Wits Trenchmour*, "a conference betwixt a scholler and an angler," and in his *Fantastickes*, a series of short prose pictures of the months, the Christian festivals, and the hours, which throw much light on the customs of the times. Most of Breton's books are very rare and have great bibliographical value. His numerous works, with the exception of some belonging to private owners, were collected by Dr. A. B. Grosart in the *Chertsey Worthies Library* in 1879.

**BRETÓN DE LOS HERREROS, MANUEL** (1796-1873), Spanish dramatist, was born at Quel (Logroño) and was educated at Madrid. Enlisting in 1812, he served against the French in Valencia and Catalonia, and retired with the rank of corporal in 1822. His first piece, *A la vejez viruelas*, was produced in 1824, and proved the writer to be the legitimate successor of the younger Moratin. During the next four years he composed 39 plays, six of them original, the rest being translations or recasts of classic masterpieces. His plays were a long series of successes. He wrote some 360 original plays, 23 of which are in prose. No Spanish dramatist of the 19th century approaches him in comic power, while his metrical dexterity is unique. *Marcela o a cual los três?* (1831), *Muérete; y verás!* (1837), and *La Escuela del matrimonio* (1852), are perhaps his best plays.

See Marqués de Molins, *Bretón de los Herreros, recuerdos de su vida y de sus obras* (1883); *Obras de Bretón de Herreros* (1883); E. Piñeyro, *El Romanticismo en España* (Paris, 1904).

**BRETON LANGUAGES:** see INDO-EUROPEAN LANGUAGES and CELTIC LANGUAGES.

**BRETON LITERATURE.** It is usual to divide Breton literature into three periods corresponding to the language—old, middle and modern. The written remains in the first period (8th to 11th centuries) consist entirely of glosses and names in ancient documents. The chief collections of glosses are (1) the Oxford glosses on Eutychius; (2) the Luxemburg glosses; (3) the Bern glosses on Virgil; (4) the Cambridge glosses on Amalarius; (5) five *Collationes Canonum*, the chief mss. being at Paris and Orleans. All the glosses have been published by Loth (*Vocabulaire Vieux-Breton*, 1884). Breton names occur in Latin lives of saints, in the Charter of Redon written in the 11th century but dating largely from the 9th, and in the Charter of Landevennec (11th century). Lists of these names occur in Loth's *Chrestomathie Bretonne*.

The Middle Breton period extends from the 11th to the 17th centuries, but down to the 15th century only proper names are found, in such official documents as the Charter of Quimperle (12th and 13th centuries), with the exception of a few scraps of verse discovered in a 14th century ms. in Paris (*Revue Celtique*, xxxiv. 241). These scraps constitute the earliest known connected text in Breton. But it is at the end of the 15th century that Breton literature can really be said to begin. To this period belong a Breton-Latin-French dictionary called the *Catholicon* of Lagadeuc, dated 1464 and printed in 1499 (the first printed Breton book) and the dictionary and conversations (French-Breton) of Quiquer de Roscoff, printed in 1626. A collection entitled *Cantiques bretons* was published in 1642 in which the names of several Breton airs are given. All the remaining works of the period are religious. Two are in prose—the *Life of St. Catherine* (1576) and the *Mirror of Confession* (1621). The former is a translation of the version found in the *Golden Legend*, and the latter a translation from French. The other works are in verse. *The Life of St. Nonn* (end of the 15th century) is a paraphrase in the form of a drama of the Latin life, with some attempts to localize a few events in Brittany. *Le Grand Mystère de Jésus* (1530) follows the French play of Arnoul Gresban and Jean Michel. This drama falls into three parts, the Passion, the Resurrection, Dialogues. *Le Mystère de Sainte Barbe* (1557) is also derived from a French play. Three long poems on the *Passing of Mary*, the *Fifteen Joys of Mary* and the *Life of Man* belong to the same period as the *Grand Mystère de Jésus*, all three probably being based on French versions. A Breton metrical version of the Creed occurs in a French mystery play dated 1456 (*Revue Celtique*, xx. 184). *Le Mirouer de la Mort* is a somewhat lugubrious poem of 3,602 lines composed in 1519 by "Maestre Jehan an Archer Coz" and printed in 1575. It is based ultimately upon a Latin work (in prose mixed with verse) of which versions exist in French. It is a description of the four destinies of man—death (lines 59-582), the last judgment (lines 583-1954), hell (lines 1955-2702), heaven (2703-3566), the remaining lines being introductory and conclusion. *Doctrin an christenien*, a translation from French, was published in 1622. The metrical *Devout Meditations* of Cadec appeared in 1651, and in the previous year a collection of carols (*An Nouelou ancien*). To the 16th century belong a Book of Hours in verse, a prose extract from the Léon missal, and also a prose catechism. The lack of originality in the Breton published works of this period is obvious. None of them can be said to reflect in any way the real Breton culture of the period. French influences are particularly evident in the enormous number of French words that appear. French was the language of the upper classes, and the predominance of religious subjects among the literary remains of the period together with the complete absence of what was truly Breton in spirit argues strongly in favour of the assumption that the indigenous culture of the country was entirely neglected by the learned classes. In view of what was to occur later in Breton literature the most significant thing among the products of the middle period is the existence of the three mystery plays already mentioned.

**The Modern Period.**—Modern Breton is considered to begin with the appearance in 1659 of Julien Maunoir's grammar, *Le Sacré Collège de Jésus*, in which he substituted for the traditional orthography a more phonetic system. This orthographical division has however practically no significance from the literary standpoint, for the same types of works continued to appear up to the 19th century. Numerous collections of religious poems and manuals of devotion in prose and verse were published. But the bulk of Breton literature in this period consisted of mysteries and miracle plays. The subjects of these plays fall into four classes: (1) Old Testament subjects; (2) New Testament subjects; (3) lives of the saints; (4) chivalry. Generally the plays are derived from French sources, and in the case of the third class from Latin lives of the saints. The treatment is invariably of the traditional style, even when the saint is Breton. Of course there is occasionally some local colouring, as could be expected, but broadly speaking the plays evince little originality. To the first class belong *Creation ar bed*, *Bue Jacob*, *Vie de Moïse*, *Vie de David*; to the second *Bue santes Anna*, *Saint Jean-Baptiste*, *La Passion*, *Vie de l'antecrist* (which treats of the Last Judgment, and in which occurs the well-known Debate of the Body and the Soul). It is but natural to find in Brittany several plays of the third class—*St. Gwenolé*, *St. David*, *St. Garan*, *St. Patrick*, etc. In the fourth class are found *Vie des quatre fils*, *Aymon* and *Huon de Bordeaux*. The following may also be noted: *Vie de Louis Eunius* (into which the legend of St. Patrick's purgatory enters), *Robert le Diable*, and the three farces *Ar Farvel goapaër* (*Le bouffon moqueur*), *Ian Mêlargé* (*Mardi-Gras*), and *La Vie de Mallargé, de Tristemine sa femme, et de ses enfants*. The actors in these plays were always peasants, and the whole movement incurred the displeasure of the clergy, with the result that the Breton stage was well-nigh killed about the middle of the 19th century. But a revival set in towards the end of the century, largely due to the inspiration of the Abbé le Bayon, founder of the Breton theatre of Ste. Anne d'Auray, and author of Breton dramas. Loth has described the 18th century as the "century of dictionaries," and little of literary importance appeared in that century. But the 19th century saw a revival of interest in Breton, largely due to the work of Le Gonidec. A real endeavour was made to create a national literature, particularly after the attention of the whole world of letters was attracted to Brittany by the publication of *Barzas Breiz*. The most prominent of the pioneers of this movement were Auguste Brizeux, F. M. Luzel and Prosper Proux. Brizeux (1803–58), better known as a French poet, wrote a collection of lyrics entitled *Telen Arvor* (1884). Luzel published original compositions under the title *Bepred Breizad, Toujours Breton* (1864). Proux published *Canacouemo grêt gant eur C'hernewod* (1838) and *Ar Bombard Kerne* (*The Hautboy of Cornouailles*, 1866). The themes tended to be conventional, and the works of these writers are somewhat monotonous. An anthology of poems connected with the movement appeared in 1862 under the title *Bleuniou Breiz, Poésies anciennes et modernes de la Basse-Bretagne*. P. D. de Goesbriand published in 1836 a Breton version of several of La Fontaine's fables, and a collection of metrical fables appeared in 1867 entitled *Marvailhou Grac'h Koz* by G. Milin. A book of Georgics, *Levr al labourer*, in the Vannes dialect, was published by the Abbé Guilleme in 1849. A translation of the Scripture prepared by Le Gonidec and revised by Troude and Milin was published in 1868.

**Ballad Literature.**—But it is the legends, folk-tales and ballads that constitute the glory of the literature of Brittany. The famous collection of ballads entitled *Barzas Breiz* was issued in 1839 by Hersart de la Villemarqué (1815–95) and immediately aroused interest and attention. Folk-poetry was the fashion at the time and de la Villemarqué set about collecting the popular poetry of his country. The material was, however, severely edited by him and several collaborators who transformed at will, expunging the crude and gross. He himself believed that the folk-songs went back to the early days of the Breton people and so were similar to the traditional Welsh poetry associated with Llywarch Hen and Taliesin. He further thought that it was possible to make them appear in their primitive dress. But criticism of his

work has been unsparing, and has shown that no trace of anything earlier than the 16th century occurs in these songs. It has made clear that songs were touched up in order to contain historical reminiscences of early times. *Barzas Breiz* (or *Barzas Breiz* from the 2nd ed. of 1867 on) therefore is no anthology of Breton popular poetry. Its contents may be divided into three classes: (1) Poems rearranged by the editor or others and consisting of love-songs and ballads. (2) Modern poems transferred to mediæval times. (3) Spurious poems dealing with such personages as Nominoë and Merlin. Its appearance caused a controversy almost as famous as that caused by Macpherson's forgeries and reminds one of the recent commotion in Wales consequent upon the exposure of Iolo Morganwg's methods. F. M. Luzel was the first scholar to publish the genuine ballad literature of Brittany. His collection appeared in two volumes bearing the title *Gwerziou Breiz-Izel, Chants populaires de la Basse-Bretagne* (1868 and 1874), and contains the original of several of the poems in *Barzas Breiz*. The *gwerziou* (*complaintes*) deal with local history (particularly crimes of various sorts), religious legends and superstitions, folk-lore. They are dramatic in composition, simple and concise in style. They display greater originality than the other type of popular poetry called *soniou*, consisting of love-songs, satires, carols and marriage-lays. French influence is often found in the *soniou*. They were first published by F. M. Luzel with the collaboration of Le Braz in two volumes with the title *Soniou Breiz-Izel, chansons populaires de la Basse-Bretagne* (1890). Luzel also collected folk-tales and legends, and published a large number of them in Breton as well as in French translations. His published collections are, *Contes bretons recueillis et traduits par F. M. Luzel* (1870), *Les Légendes chrétiennes de la Basse-Bretagne* (1881) and *Veillées bretonnes, moeurs, chants, contes et récits populaires des Bretons-Armoricains* (1879). Another collector of Breton legends was Anatole le Braz. He was commissioned to investigate the stories current with reference to *An Ankou* (death), and his results are found in his *La Légende de la mort* (1912–13). Other collections are *Ar marvailher brezounek* (1870) by Troude, *Pipi Gonto* (2 vols., 1902, 1908) by A. le Moal, and *Marvailhou ar Vretoned* (1907) by C. M. le Prat.

**Growth of National Feeling.**—A new movement started in the '90s of last century which was remarkably prolific. Reference has already been made to the revival of drama; many of the dramatic works were crude, and largely propagandist. On the other hand the poetry produced was distinctly better than that of the earlier part of the century. The leading figure of the period was Jaffrennou (*Taldir*), author of two striking volumes of lyrics—*An Hirvoudou* ("Sighs," 1899), *An Delen Dir* ("The Harp of Steel," 1900)—and *Barzas Taldir* (3 vols.). A greater artist is Erwan Berthou. C. M. de Prat, J. Cuillandre and N. Quellien may also be mentioned. An anthology of lyrics appeared in 1902 under the title of *Bleuniou Breiz-Izel, Dibab Barzomezou*. The literature of the period is clear evidence of the growth of national feeling in Brittany. This feeling is becoming more pronounced, and with the profounder awakening of national consciousness Breton literature grows richer. One of the outstanding figures in recent Breton literature was Jean-Pierre Calloc'h, who was killed in action in 1917, a grave loss to Breton letters. His works were published (with a French version) in 1921 under the title *A Genoux*. He wrote in the Vannes dialect, and his works display his profound love of country and his mystic qualities. Another sign of awakening is the attempt to enrich the vocabulary in order to extend the use of the language by the creation of new terms. This is very much in evidence in the "archæological" romance entitled *Skeila Segobrani*. On the other hand we find the attempt to restore earlier Breton words with the necessary changes deduced by so-called phonetic "laws" and similarly to "bretonize" Welsh words. This is seen in J. le Roux's Breton version of the mediæval Welsh romance of *Peredur fab Efwrawg*; the translator has also attempted to fashion an orthography which will make the work easily legible to speakers of all the Breton dialects (*Le roman de Pérédur, texte gallois traduit en breton*, par J. le Roux, Rennes, 1923). Several collections of tales have been recently published, chiefly collected from the various periodicals. It is interesting to

note that, in addition to the translation of *Peredur* referred to already, other works are being turned into Breton, such as Synges's *Riders to the Sea* (*War varc'h d'ar mor*) and the Irish story *Oidhe Chloinne Tuireann* (*Tonkadur Bugale Tuireann*). The present awakening in Breton literature owes much to the incessant work of François Vallée and the scholarly work of Prof. Émile Ernault.

**BRETONNEAU, PIERRE** (1778–1862), French physician, was born on April 3, 1778, at Tours, and died on Feb. 18, 1862. His fame rests on the first performance (1825) of the operation of tracheotomy for croup; on the clinical distinction of diphtheria, so-named by him in his *Des inflammations spéciales du tissu muqueux et en particulier de la diphthérie* (1826); and on his work on typhoid, which, he foresaw, would be differentiated from typhus. In 1855 he stated the germ theory of disease.

See P. Triaire, *Bretonneau et ses correspondants* (1892).

**BRETSCHNEIDER, KARL GOTTLIEB** (1776–1848), German theologian, was born at Gersdorf (Saxony), on Feb. 11, 1776. He lectured on philosophy and theology at Wittenberg (1804–06), was pastor of Schneeberg, Saxony (1806–08), superintendent at Annaberg, Saxony (1808–16), and then removed to Gotha, where he was general superintendent until his death (Jan. 22, 1848). The best part of his life's work was done at Gotha.

In 1820 appeared his treatise on the Gospel of St. John, entitled *Probabilia de Evangelii et Epistolarum Joannis Apostoli indole et origine*, which discussed with marked moderation the arguments against Johannine authorship. Bretschneider announced in the preface to the second edition of his *Dogmatik* in 1822, that he had never doubted the authenticity of the gospel, and had published his *Probabilia* only to draw attention to the subject, and to call forth a more complete defence of its genuineness. His greatest contribution to exegesis was his *Lexicon Manuale Graeco-Latinum in libros Novi Testamenti* (1824), valuable for its use of the Greek of the Septuagint, of the Old and New Testament Apocrypha, of Josephus, and of the apostolic fathers, in illustration of the language of the New Testament. In 1826 he published *Apologie der neuern Theologie des evangelischen Deutschlands*. An English translation of his *Manual of the Religion and History of the Christian Church* appeared in 1857. His dogmatic position seems to be intermediate between the extreme school of naturalists, such as Heinrich Paulus, J. F. Röhr and Julius Wegscheider on the one hand, and D. F. Strauss and F. C. Baur on the other. Recognizing a supernatural element in the Bible, he nevertheless allowed a full critical exercise of reason in the interpretation of its dogmas (cf. O. Pfleiderer, *Development of Theology*).

See his autobiography, *Aus meinem Leben: Selbstbiographie von K. G. Bretschneider* (Gotha, 1851) (trans. G. E. Day, 1852–1853); Neudecker in *Die allgemeine Kirchenzeitung* (1848), No. 38; Wüstemann, *Bretschneideri Memoria* (1848); A. G. Farrar, *Critical History of Free Thought* (Bampton Lectures, 1862); Herzog-Hauck, *Realencyklopädie* (ed. 1897).

**BRETWALDA**, a title meaning "Ruler of Britain," applied by the *Anglo-Saxon Chronicle* to Egbert, king of the West Saxons, when he became overlord of all the English peoples south of Humber. The chronicler states that seven other kings, from Aella of Sussex in the 5th century to Oswiu of Northumbria in the 7th, had held this title before Egbert. It was a poetical expression, not a formal style, and is therefore not found in Latin documents of an earlier time.

**BREUGHEL** (or BRUEGHEL), **PIETER**, Flemish painter (1525–1569), the son of a peasant of Breughel, near Breda, was taught by Koek, whose daughter he married. He spent some time in France and Italy, and then went to Antwerp, where he was elected into the Academy in 1551. He finally settled at Brussels and died there on Sept. 5, 1569. The subjects of his pictures are chiefly humorous figures, like those of D. Teniers; and if he lacks

the delicate touch and silvery clearness of that master, he has abundant spirit and comic power.

The best collection of Brueghel's work is in the Vienna gallery, but there is an excellent example, "The Adoration of the Kings," in the National Gallery, London. Sir Charles Holmes (*National Gallery*, vol. ii.) observes that Brueghel pointed the way to a more rapid and fluent brushwork, and is the connecting link between the early Netherlandish painters and the epoch of Rubens, Van Dyck and Jordaens.

His son **PIETER**, the younger (1564–1637), known as "Hell" Brueghel, was born in Brussels and died at Antwerp, where his "Christ bearing the Cross" is in the museum.

Another son, **JAN** (c. 1569–1642), known as "Velvet" Brueghel, born at Brussels, first painted flowers and fruits, and afterwards landscapes and sea-pieces. Rubens made use of him in the landscape part of several of his small pictures—such as his "Vertumnus and Pomona," the "Satyr viewing the Sleeping Nymph," and the "Terrestrial Paradise."

See Van Bastelaer and de Loo, *Pieter Brueghel l'ancien, sa vie et son oeuvre* (1905–07).

**BREVE**, in music, the note of greatest time-value (the equivalent of two semibreves) in our existing Western notation, represented by the sign  $\text{||}$  or  $\text{=}$ . It is, however, now seldom used, the semibreve having taken its place for practical purposes, although it is not quite obsolete, Brahms for instance having employed it in his *German Requiem*. Formerly there were other notes longer still, namely, the large or maxima and the long or longa; in contrast with which the breve (brevis, brief) received its name, but these disappeared many centuries ago. (See **MUSICAL NOTATION**; **HARMONY**.)

**BREVET** (a diminutive of the Fr. *bref*), a short writing, originally an official writing or letter, with the particular meaning of a papal indulgence. The use of the word is mainly confined to a commission, or official document, giving to an officer in the army a permanent, as opposed to a local and temporary, rank in the service higher than he holds substantively in his corps. In the British army "brevet rank" exists only above the rank of captain, but in the United States army it is possible to obtain a brevet as first lieutenant. In France the term *breveté* is particularly used with respect to the general staff, to express the equivalent of the English "passed staff college" (p.s.c.).

**BREVIARY**, the book which contains the daily service for the canonical hours in the Roman Catholic Church (Lat. *brevarium*, abridgment, epitome). It includes psalms, lessons, antiphons, etc., for every day in the year; but excludes the Eucharistic office (contained in the Missal) and the rites of baptism, marriage, ordination, etc. (which are found in the Ritual or the Pontifical). In the early days of Christian worship the Bible furnished all that was required, containing as it did the books from which the lessons were read and the psalms recited. The first step in the evolution of the Breviary was probably the separation of the Psalter into a choir-book. The monastic practice of daily reciting the 150 psalms took so much time that the monks began to spread it over a week, dividing each day into hours, with its allotted psalms for each hour. St. Benedict in the 6th century drew up such an arrangement, and the Roman division, which remained practically unchanged until 1912, is perhaps even older. To the Psalter were added, in course of time, other service-books, containing prayers, antiphons, etc. Jean Beleth, a 12th-century liturgical author, gives a long list of books needful, besides the Psalter and Old and New Testaments, for right conduct of the canonical office:—Antiphonary, Passionary, Collectar, etc. The inconvenience of using such a library naturally led to the substitution of one compendious volume. Attempts in this direction were made as early as the 8th century by Alcuin, and a little later by Prudentius, bishop of Troyes; Gregory VII. (pope 1073–85) simplified the liturgy used at the Roman court, and gave his abridgment the name of Breviary. But the earliest extant ms. containing the whole canonical office is of the year 1099 (from Monte Cassino, now in the Mazarin library). A few 12th century Breviaries are extant, all Benedictine; but under Innocent III. (pope 1198–1216) their use began to be more general. The

Breviary of the Roman court was adopted (with some modifications, e.g., the substitution of the "Gallican" for the "Roman" version of the psalms) by the newly founded order of Franciscan friars, with the authorization of Gregory IX. (1227-41); and through their wide-ranging activity it became known all over Europe, and supplanted the older partial books. Nicholas III. (1277-80) introduced the Franciscan Breviary for the Roman churches, and thus made its position secure. It did not, however, supersede the various local diocesan Breviaries until 1568, when Pius V. issued it in a revised form, and made it obligatory in every diocese where the local use could not show at least 200 years of existence; and since then it has gradually become universal except in the Benedictine, Dominican and some other religious orders, in the diocese of Milan (where the Ambrosian use persists), and in the cathedrals of Toledo and Salamanca (where the Mozarabic use, once universal throughout Spain, is still followed). Of the many revisions of the Roman Breviary the most remarkable is that by Cardinal Francis Quiñones (1535), which, undertaken by order of Clement VII., passed through many editions before its suppression in 1568, and was largely used by the compilers of the English Prayer Book of 1549. The Plan Breviary was altered by Clement VIII. in 1602 (through Baronius and Bellarmine), especially as concerns the rubrics; and by Urban VIII. (1623-44), a purist who unfortunately tampered with the text of the hymns, injuring both their literary charm and their historic worth.

In the 17th and 18th centuries a movement of revision, largely under Gallican and Jansenist influences, but also in the interests of sound critical scholarship, took place in France, and succeeded in modifying about half the Breviaries of that country. These reformed French Breviaries—e.g. the Paris Breviary of 1680 by Archbishop François de Harlay (1625-95) and that of 1736 by Archbishop Charles Gaspard Guillaume de Vintimille (1655-1746)—show a deep knowledge of Holy Scripture, and much careful adaptation of different texts; but during the pontificate of Pius IX. a strong Ultramontane movement arose against them. This was inaugurated by Montalembert, but its literary advocates were chiefly Dom Guéranger, a learned Benedictine monk, abbot of Solesmes, and Louis Veuillot (1813-83) of the *Univers*; and it succeeded in suppressing them everywhere, the last diocese to surrender being Orleans in 1875. The Jansenist and Gallican influence was also strongly felt in Italy and in Germany, where Breviaries based on the French models were published at Cologne, Münster, Mainz and other towns. Meanwhile, under the direction of Benedict XIV. (pope 1740-58), a special congregation collected many materials for an official revision, but nothing was published. In 1902, under Leo XIII., a commission under the presidency of Monsignor Louis Duchesne was appointed to consider the Breviary, the Missal, the Pontifical and the Ritual. The findings of this commission have not been published; but Pius X., by the Apostolical Constitution "Divino Afflatu" (Nov. 1, 1911), ordained (as from Jan. 1, 1913) the use of a newly-arranged Psalter, as well as the observance of certain new regulations in the manner and order of reciting the office—the main object of the changes being to restore the weekly recitation of the entire Psalter.

The beauty and value of many of the Latin Breviaries were brought to the notice of English churchmen by one of the numbers of the Oxford *Tracts for the Times*, since which time they have been much more studied, both for their own sake and for the light they throw upon the English Prayer Book.

From a bibliographical point of view some of the early printed Breviaries are among the rarest of literary curiosities. Being merely local, the copies were not spread far, and were soon worn out by daily use. Doubtless many editions have perished without leaving a trace of their existence, while others are known by unique copies. In Scotland the only one which has survived the convulsions of the 16th century is that of Aberdeen, a Scottish form of the Sarum Office, revised by William Elphinstone (bishop 1483-1514), and printed at Edinburgh in 1509-10 (the Sarum Rite was much favoured in Scotland as a kind of protest against the jurisdiction claimed by the church of York). Four copies have

been preserved, and it was reprinted in 1854 for the Bannatyne Club. It is particularly valuable for the notices of early Scottish history embedded in the lives of the national saints. Though enjoined by royal mandate in 1501 for general use within the realm of Scotland, it was probably never widely adopted. The new Scottish *Proprium* sanctioned for the Roman Catholic province of St. Andrews in 1903 contains many of the old Aberdeen collects and antiphons.

The Sarum Breviary itself, originally compiled by St. Osmund (bishop of Salisbury 1078-99) was very widely used. Many editions were printed in the 15th and 16th centuries. Other English uses are those of York (observed in the northern province) and Hereford.

**Contents of the Roman Breviary.**—The Breviary is sometimes found in one volume, sometimes in two; but usually it is in four volumes, for the winter, spring, summer and autumn portions of the ecclesiastical year (which begins with the first Sunday in Advent). After the calendar, tables for finding Easter, general rubrics and other prefatory matter, each volume contains (1) Psalter; (2) *Proprium de Tempore*; (3) *Proprium Sanctorum*; (4) *Commune Sanctorum*; (5) Extra Services.

1. *Psalter*.—The psalms arranged in sections, with prayers, hymns, antiphons, etc., for the several hours throughout the week. In the new Breviary the psalms are arranged so that the whole psalter may be recited each week, and (by dividing some of the longer psalms) that the portion allotted to each day's office may be of approximately the same length (e.g., the quota for Matins is nine psalms of 15 verses each). Psalms cxlviii.-cl. are always used at Lauds, and give that office its name. The text of the psalms is that commonly known as the Gallican, i.e. St. Jerome's second revision of the Old Latin version. This was adopted at Rome in the 13th century (having long been accepted elsewhere) instead of his first revision, the so-called Roman version, which is still used in St. Peter's.

2. *Proprium de Tempore*.—The lessons, little chapters, and special antiphons, etc., for every Sunday and week-day throughout the ecclesiastical season.

3. *Proprium Sanctorum*.—The like for saints' days and other festivals determined by the day of the month. The lessons consist largely of summaries of the saints' lives, and this part of the Breviary, though revised from time to time, is often criticized adversely as containing historical inaccuracies. As about 90% of the days in the year have, during the course of centuries, been allotted to some saint or other, it is easy to see how this section of the Breviary has encroached upon the *Proprium de Tempore*. This has long been one of the chief problems involved in a revision of the Breviary; it is dealt with to some extent in the reformed Psalter of Pius X.

4. *Commune Sanctorum*.—Offices for feasts of various groups or classes of saints (apostles, evangelists, martyrs, etc.), for the dedication of a church, and for feasts of the Blessed Virgin Mary. These offices are of very ancient date.

5. *Extra Services*.—These include the Little Office of the Blessed Virgin Mary, the Office of the Dead and offices peculiar to each diocese.

It has already been indicated, by reference to Matins, Lauds, etc., that not only each day, but each part of the day, has its own office, the day being divided into liturgical "hours." A detailed account of these will be found in the article HOURS, CANONICAL. Each of the hours of the office is composed of the same elements, viz. psalms (including canticles), antiphons, responses, hymns, lessons, little chapters, versicles and collects.

The *psalms* have already been dealt with.

The Psalter of the Breviary also includes seven Old Testament canticles for use of Lauds, viz. the Song of the Three Children (Dan. iii. 57-88, on Sunday), Song of Isaiah (Is. xii., Monday), Song of Hezekiah (Is. xxxviii. 10-20, Tuesday), Song of Hannah (1 Sam. ii. 1-10, Wednesday), Song of Moses (Exod. xv. 1-19, Thursday), Song of Habakkuk (Hab. iii., Friday), Song of Moses (Deut. xxxii. 1-43, Saturday), and three from St. Luke, viz. the Benedictus (i. 68-79) at Lauds, Magnificat (i. 46-55) at Vespers, and Nunc Dimittis (ii. 29-32) at Compline.

The *antiphons* are short liturgical forms, of biblical or patristic origin, used before and after a psalm. The term originally signified a chant by alternate choirs, but has quite lost this meaning in the Breviary.

The *responsories* and *versicles* are similar in form to the antiphons, and are used with them before and after psalms, also after the lessons and little chapters, and sometimes after prayers.

The *hymns* are short poems going back in part to Prudentius and Ambrose. Together they make a fine collection, despite Urban VIII.'s misguided attempts to improve them.

The *lessons* are drawn from the Bible, the Acts of the Saints, and patristic homilies. In the lessons, as in the psalms, the order for special days breaks in upon the normal order of ferial offices and dislocates the scheme for consecutive reading. The lessons are read at Matins (which on Sundays and feast-days is subdivided into three nocturns).

The *little chapters* are very short lessons read at the other "hours."

The *collects* come towards the close of the office and are short prayers summing up the supplications of the congregation. They are largely drawn from the Gelasian and other Sacramentaries.

Every clerk in orders and every member of a religious order must publicly join in or privately read aloud (*i.e.*, using the lips as well as the eyes) the whole of the Breviary services allotted for each day. Laymen do not use the Breviary to any great extent.

The Roman Breviary has been translated into English (by the marquess of Bute in 1879; new ed. with a trans. of the Martyrology, 1908), French and German. The English version is noteworthy for its inclusion of the skilful renderings of the ancient hymns by J. H. Newman, J. M. Neale and others.

Batiffol, *L'Histoire du bréviaire romain* (3rd ed., Paris, 1911; Eng. tr.); Baudot, *Le Bréviaire romain* (1907). A complete bibliography is appended to the article by F. Cabrol in the *Catholic Encyclopaedia*, vol. ii. (1908). For the reforms introduced by Pius X. see *Cath. Enc.*, vol. xvi. (1914), pp. 13-14; E. Burton and E. Myers, *The New Psalter and its use* (1912); E. J. Quigley, *The Divine Office: a study of the Roman Breviary* (1920).

**BREVARY OF ALARIC** (*Breviarium Alaricanum*), a collection of Roman law, compiled by order of Alaric II., king of the Visigoths, in the year 506. It comprises 16 books of the Theodosian code; the *Novels* of Theodosius II., Valentinian III., Marcian, Majorianus and Severus; the *Institutes* of Gaius; five books of the *Sententiae Receptae* of Julius Paulus; 13 titles of the Gregorian code; two titles of the Hermogenian code; and a fragment of the first book of the *Responsa Papiniani*. From the circumstance that the *Breviarium* has prefixed to it a royal rescript (*commonitorium*) directing that copies of it, certified under the hand of Anianus, should be received exclusively as law throughout the kingdom of the Visigoths, the compilation of the code has been attributed to Anianus by many writers, and it is frequently designated the Breviary of Anianus (*Breviarium Aniani*). The code, however, appears to have been known amongst the Visigoths by the title of "*Lex Romana*," or "*Lex Theodosii*," and it was not until the 16th century that the title of "*Breviarium*" was introduced to distinguish it from a recast of the code, which was introduced into northern Italy in the 9th century for the use of the Romans in Lombardy. This recast of the Visigothic code has been preserved in a ms. known as the Codex Utinensis, which was formerly kept in the archives of the cathedral of Udine, but is now lost; and it was published in the 18th century for the first time by P. Canciani in his collection of ancient laws entitled *Barbarorum Leges Antiquae*. Another ms. of this Lombard recast of the Visigothic code was discovered by Hänel in the library of St. Gall. The chief value of the Visigothic code consists in the fact that it is the only collection of Roman Law in which the five first books of the Theodosian code and five books of the *Sententiae Receptae* of Julius Paulus have been preserved, and until the discovery of a ms. in the chapter library in Verona, which contained the greater part of the *Institutes* of Gaius, it was the only work in which any portion of the institutional writings of that great jurist had come down to us. See GERMANIC LAWS, EARLY.

The most complete edition of the *Breviarium* will be found in the collection of Roman law published under the title of *Jus Civile Ante-Justinianum* (Berlin, 1815). See also G. Hänel's *Lex Romana Visigothorum* (Berlin, 1847-49).

**BREVIER**, a printing type ("8 point"), smaller than bourgeois and larger than minion, which derives its name from its original use in breviaries. The following passage is set in brevier type:

William Caxton, the first English printer, was born in the Weald of Kent, perhaps at Tenterden. The name, which was apparently pronounced Caxton, is identical with Causton, the name of a manor in the parish of Hadlow.

In France, brevier type is called *petit texte*. (See PRINTING TYPE.)

**BREWER, JOHN SHERREN** (1810-1879), English historian, was born at Norwich, the son of a Baptist schoolmaster. He was educated at Queen's college, Oxford, was ordained in the Church of England in 1837, and held various preferments and lectureships. The introductions to his *Letters and Papers of the Reign of King Henry VIII.*, which were published separately, under the title *The Reign of Henry VIII.*, in 1884, form a scholarly and authoritative history of Henry VIII.'s reign. He died at Toppesfield, Essex.

**BREWER**, a city of Penobscot county, Maine, U.S.A., on the east bank of the Penobscot river, opposite Bangor, with which it is connected by ferry and trolley. The population in 1930 was 6,329. At one time it had eight ship-building yards, and formed with Bangor the chief lumber-shipping port of the country. Its present industries include a large pulp and paper mill, brick-works with an annual output of 2,000,000 to 5,000,000 and a tannery which receives 1,400 dozen sheepskins a week from South America and New Zealand. Brewer was settled in the 18th century, separated from the town of Orrington and incorporated as a town in 1812, and received a city charter in 1889. It was named after its first postmaster, Col. John Brewer.

**BREWING**, the manufacture of the alcoholic beverage beer, mainly from cereals (chiefly malted barley), hops and water. Though no doubt originally largely a domestic, and later a monastic industry, brewing is to-day almost entirely in the hands of commercial firms. Until about the 12th or 13th centuries the preparation of beer on anything like a manufacturing scale appears to have been carried on in England mainly by the monasteries. As beer (*q.v.*) was in the middle ages the chief drink for breakfast, dinner and supper it must have developed into a great trade as the towns grew. Its importance in London may be gauged by the record of 300 brewers in the City and its liberties in 1419. Among the most cherished possessions at Brewers' Hall is the old book of the Brewers' Company containing its records from 1418 to 1440 and reputed to be the oldest company's book in existence. During the 15th century the spirit of craftsmanship was developing and in 1438 the Brewers, who were formerly the Guild of Our Lady and St. Thomas à Becket, were incorporated by letters patent as the Wardens and Commonalty of the Mystery of Brewers of the City of London. The brewery at Queen's college, Oxford, briefly described later in this article, remains as an example of what these were several hundred years ago. Until the 18th century the wealthier classes generally brewed their own beer, but then it gradually became more usual to have it brewed for them at a regular brewery. This tendency to centralize brewing became continually more marked. The number of farmers who brewed for their own labourers and of publicans who brewed for sale diminished every year, the latter a great deal more rapidly as the tied-house system spread during the latter half of last century. In the year 1894-95, in England 8,863 licences were issued to brewers for sale, but by 1904-05 this number had been reduced to 5,164. Amalgamations and absorptions of the smaller public brewers by the larger concerns has gone on hand in hand with the extinction of the private brewers and is still going on. The number of licences for brewers for sale issued in 1914 was 3,746 and in 1927 (excluding Irish Free State) 1,722. Many of the present large firms in England were taking their shape and the names under which they are now known during the 18th century.

In the British Isles brewing is almost confined to top fermented malt beverages among which the India pale ales and strong ales

of Burton-on-Trent, the stouts and porters of London and Dublin, light bitter and mild ales are typical examples. The essential difference between pale, light bitter and mild ales lies in the flavour and colour which depend particularly on the type of malt and quantity of hops used in brewing them. Porter and stout differ from these in that a proportion of brown and black malt is used to give the black colour which is accompanied by a full, rich flavour. Beers of varying strength are brewed in each of the types mentioned, and some details of their composition are given in the article BEER.

In Continental Europe and America lager or bottom fermentation beer largely superseded the earlier "ales." Three characteristically different types, the pale Pilsener, the medium Vienna and the dark Munich beers, typical of the three great brewing centres, soon stood out as examples which were followed and copied throughout the brewing world, though many developments were made in the original brewing processes, particularly in America.

All these beers are sold both in cask and bottle. A very great increase in the proportion bottled has occurred during recent years, and this has led to important developments in brewing and bottling processes.

**Materials Used in Brewing.**—The essential materials are water, malt and hops. The experiences of many centuries has shown that barley malt (*q.v.*) is the most suitable source of the extractives which supply the nutrient constituents of beer. The types of barley used for malting will be found described under MALT and BARLEY and it will be sufficient to mention here that brewers find it advisable to blend malts from barleys grown in different localities and countries. It is not often found possible to produce satisfactory light ale or beer from malted English barley only; an admixture of grain from drier, sunnier climates is almost always advisable. A large proportion of such barley, grown in California, North Africa, Chili, Asia Minor and elsewhere, is of the "six-rowed" varieties in contradistinction to the "two-rowed" varieties in which are comprised English malting barleys and a great deal from the Continent. It is more husky than the European two-rowed barley and materially assists the drainage, which is an essential part of the mash-tun operations.

Malt of different characteristics and qualities is used according to the nature of the beer required. The "grist" for stout is made up of malt similar to that used in pale and mild ales blended with malt which has been more highly kilned or roasted in cylinders, or with roasted barley. Details of the methods used for producing the various types of malt are given in the articles on MALT and MALTING.

As the extractives of malt consist so largely of sugars and other carbohydrates produced by the conversion of the starch of the grain in the mash-tun, through the influence of "starch-converting" or "saccharifying" enzymes (*q.v.*) known as "diastase" also contained in the malt, their partial replacement in the wort by similar sugars obtained either from external sources, or actually in the mash-tun from unmalted cereals is reasonable. The use of such substitutes for malt is in large measure limited by the lack of malt flavour that their use in undue quantity would entail, by the difficulty of converting an undue proportion of unmalted cereal starch by the diastase of the malt with which it is mixed—the only permissible means of conversion; and the lack of soluble nitrogenous substances which are yielded by malt to the wort and which are necessary for the development of yeast and are among the essential constituents of beer.

Malt extract made from malt by a mashing process similar to that of the brewery, but designed to retain the enzymes of the malt in a condition of high activity, followed by evaporation to a syrup of the wort under reduced pressure, is sometimes used in the mash-tun or copper to provide additional diastase or yeast nutrients when either of these are lacking in the grist employed.

The unmalted grain substitutes, or malt adjuncts, most commonly used are maize grits, and flaked maize or rice with much smaller quantities of unmalted barley and oats. The maize is degermed in order to remove the oil, and then used as grits, or, after a special treatment comprising soaking, steaming and drying on steam heated rolls, as flakes. Rice is similarly flaked.

Oats are occasionally used as oatmeal or as oat malt in stout. In America much larger quantities of rice or maize were formerly used in some beers than is customary in England.

The sugars chiefly employed are cane sugar, invert sugar (*q.v.*) and glucose with lactose, or milk sugar, to a much smaller extent. The cane sugar is generally partially refined and selected for its luscious flavour. The glucose is manufactured by the conversion of maize or other cereal starch and is generally completely converted, though partially converted products containing dextrin and maltose are also used.

Hops described elsewhere in a special article are used for the production of the aroma and bitter flavour, also on account of their dietetic qualities, and because they contain various preservative substances associated with the soft resins. The most important of these active principles are the bitter acids Humulon and Lupulon. They retard the rapid development of micro-organisms which would turn beer sour or otherwise make it undrinkable. Hops have also certain mechanical uses in the copper in which they are boiled with the wort. They help in the coagulation of various colloidal protein substances and afterwards act as a filter bed in the hop-back for the removal of the coagulum previous to cooling and fermentation of the wort. The brewing value of hops therefore depends on their flavour-giving qualities, their preservative properties and the condition of the cones in regard to their compactness and unbroken state. Their colour and freedom from disease and foreign matter are also of importance. The characteristic differences in flavour and preservative power between various varieties of British hops such as Goldings, Fuggles, Bramblings, etc. and, more particularly, between these and American and Continental hops make careful selection necessary and almost invariably a blend of several types is employed to secure the beer flavour desired. As the essential oils of hops, to which their aroma is due, are volatile and to a large extent dissipated during boiling in the copper, hop oil is extracted and sometimes added in small quantity to beer in conditioning tanks to increase the hop aroma.

No other materials are used in the manufacture of beer than those mentioned, namely water, malt, hops, raw and prepared grain and sugar. The following substances used in the course of brewing can hardly be classed as brewing materials. Certain salts, particularly gypsum, are added to the water in small quantities to make up for deficiencies in the mineral constituents of the supply. Finings, made by dissolving isinglass in water acidulated with tartaric or sulphurous acid are used as a clarifying agent. Caramel made from glucose or cane sugar by heating processes, is used in small quantities to adjust the colour of beer to that demanded by customers. The main source of colour in beer is the malt, and in the case of stout roasted malt or barley. The only preservative permitted in Great Britain is sulphur dioxide added in the form of sulphurous acid or its salts. The quantities permitted are fixed by the food laws of the different countries.

It was not until 1847 that the use of sugar was permitted in brewing in Great Britain. Previous to Oct. 1880 duty was charged on the malt used, but by the Finance Act of that year, commonly known as Gladstone's Free Mash-tun Act, it was transferred to the wort produced and is now only charged on the malt under certain definite conditions referred to in the section on beer duty. One result of the transfer of the duty from the malt to the product was to enable brewers to make use of reasonable substitutes. This freedom in the choice of materials has continued down to the present day, with the exception that the use of "saccharin," a coal tar product, was prohibited in 1888 on the ground that it gave an apparent palate to beer equal roughly to 4° in excess of its real gravity, the revenue suffering thereby. It has greatly helped brewers in the production of the light, bright and sparkling beers demanded to-day. Despite this, large quantities of beer and stout are made from malt and hops alone.

A fact that is frequently overlooked is that of the 11 million cwt. of malt used annually in Great Britain about 3 million cwt. is returned to the farmer as cattle food. This has a higher food value than the original barley due to the removal of starch by

the brewer and consequent concentration of protein and fat in the grains. This food is of great value for milk production.

**Brewing Waters.**—The assurance of an adequate and suitable water supply, not only for brewing but also for cleansing and steam-raising purposes is among the first considerations in the establishment of a brewery. Unimpeachable purity is always demanded, and it has long been recognized that suitability for brewing depends on the nature of the saline constituents. Many well known brewing centres have become noted for particular types of beer and this can in some measure be ascribed to the water used. Typical analyses of waters from Burton-on-Trent and from Dublin indicate that brewing waters differ very widely. That from the wells of Burton-on-Trent is particularly hard, with a large amount of permanent hardness, while that from Dublin, and those from Munich and Pilsen, are comparatively soft.

Examination of the waters of Burton-on-Trent and Dublin would seem to indicate that hard gypseous water is most suitable for pale ales and beers, and soft water for dark beers and stout.

An explanation of the different results obtained by the use of different waters is found in the interaction of the salts dissolved in the water with certain of the constituents of malt, in particular in their effect on the natural slight acidity of the malt, which has an important bearing on the starch-converting and proteoclastic enzymes of the latter. Enzymes are very sensitive to the conditions of temperature and also of reaction (acidity, neutrality or alkalinity) existing in the medium in which they occur. In the brewer's mash-tun these conditions are important factors in the influencing of the nature of products obtained from the malt and hence the character of the resulting beer. For each enzyme there is a range of reaction, usually a very slight acidity, within which it is most active. This acidity is not measured by the amount of alkali required to neutralize it, for a trace of a strong acid, such as sulphuric or hydrochloric acid, has a much greater effect than its equivalent of a weaker acid, such as acetic or lactic. It is measured by the extent to which the acid or, it may be, acid salt, is dissociated in solution, actually by the proportion of the hydrogen "ions" which it gives. This is called the "hydrogen ion" (*q.v.*) concentration of the solution and is denoted by the sign pH devised by Sørensen. The purest distilled water obtainable is dissociated to a very slight extent and has a hydrogen ion concentration denoted by  $\text{pH}=7.07$ . This signifies neutrality. Increasing hydrogen ion concentrations are represented by pH values less than this, that, for instance, existing in a very dilute or  $\frac{1}{100,000}$  normal solution of a strong mineral acid by  $\text{pH}=5$ . Though real acidity is attributed to hydrogen ions these still exist in alkaline solutions, but in smaller concentration, represented by pH values greater than 7.

Though such slight acidities as are here dealt with are quite beyond our sense of taste they are of great importance in all reactions brought about by enzymes or micro-organisms, and, consequently, in the mash-tun and during fermentation. The optima for the starch converting and proteoclastic enzymes of malt are in the region of  $\text{pH}=5$  and it is found that the most satisfactory results are obtained in the mash-tun when the reaction of the mash is about that represented by  $\text{pH}=5$  or 5.5. During fermentation there is a rise of acidity, and it is found that beer has a greater resistance to bacteria if its pH reaches about 4 than if its hydrogen ion concentration is less, the growth of the bacteria being hindered by the slight acidity while they thrive in media more closely approaching neutrality.

The saline constituents of the brewing water play a fundamental part in the attainment of the desired pH in the mash-tun. The existence of any salts which would counteract the necessary acidity is harmful. Among such salts are the bicarbonates of calcium and magnesium. It is for this reason that these salts, which form temporary hardness in water, have always been removed from brewing liquor to a greater or less extent, generally by boiling previous to mashing, or more recently by partial neutralization. The effect of gypsum is best considered from the point of view of its reaction with certain important constituents of malt, namely the primary and secondary phosphates of which the former gives a large part of its acidity to

malt, and the latter tends to produce too great an alkalinity in the wort. Gypsum converts the secondary phosphate to the primary or acid salt and in so doing increases the hydrogen ion concentration of the wort and brings it more closely towards the optimum for the activity of the enzymes. The result is a more complete extraction of the malt in the mash-tun and a greater conversion of the starch to fermentable sugars, with fuller proteolysis if the temperature is not too high. Alkaline salts have a reverse effect and restrict the conversion of starch and proteins. Other effects are produced by mineral constituents of the water apart from those due to hydrogen ion concentration. Sodium chloride, common salt, in small amount, may, for instance, tend to give a fuller flavour. The extraction of bitter substances from the hops may be increased or decreased. This effect on hop flavour is very marked with an alkaline water which would give a very harsh flavour with an amount of hops, or variety of hops, which would communicate a delicate bitter to a beer brewed with a gypseous water. It is also believed that certain of the salts present in water, magnesium sulphate, for instance, are requisite for the healthy development of yeast.

This brief description of some of the effects of the water used on the quality of the beer produced will indicate how very important this factor is in brewing. Brewers usually draw their supplies from wells or deep bores but many now use the drinking supply of their district. When the water does not contain the saline constituents thought to be desirable for the type of beer produced, the lack is made up by the addition of gypsum and other salts. The necessity for a definite acidity in the mash-tun being recognized and failing its attainment by adjustment of liquor and materials, there appears to be no obvious reason why this adjustment should not be made in the mash-tun as an alternative to water treatment. This is a most delicate process as any excess of acidity is more harmful than the slight lack that may exist. It is, however, carried out with success in some breweries in Continental Europe and in many distilleries. The usual process is the production of a definite amount of lactic acid in a small portion of the mash by means of a lactic acid bacterium, *Bacillus Delbrücki*, and the subsequent addition of this soured mash to the main mash. Water treatment is, however, generally recognized as the simpler method.

#### BREWING PROCESSES

Broadly speaking there are two main brewing processes denoted by the terms "top" and "bottom" fermentation respectively. They differ in that the yeast rises to the top of the wort after fermentation and can be skimmed off in the former or settles to the bottom of the fermenting vessels in the latter. They also differ in that fermentation is carried out at temperatures ranging from about 58° to 70° F in the top fermentation process and from about 40° to 55° F in the bottom fermentation process. It is also customary to store the beer produced by the latter process for some weeks or months in large "lager" casks or tanks in cellars kept at about the freezing point of water. In consequence, it is generally known as the "lager" process and the beer as "lager" beer. In England almost all the beer produced is brewed by the top fermentation process, only about half a dozen firms brewing lager beer. On the Continent and in most other countries lager beer has to a very large extent displaced top fermentation ale. The system of mashing also differs in typical top and bottom fermentation breweries. The former use an infusion system, the latter a decoction process and in view of this difference there are differences in detail in malting practice, and in the characteristics of the malt employed in the two processes.

**Top Fermentation or Ale Brewing.**—A typical top-fermentation brewery contains, in addition to the rooms and cellars with the machinery and vessels needed for the brewing operation, a large installation of power and heating plant. It may be arranged on a "Tower system" in which all materials employed (water, malt, hops, etc.) are first pumped or hoisted to the highest point, the wort or beer passing from stage to stage by gravitation. In larger plants this is generally not feasible and pumps are installed at one or more points to raise materials or wort as required

The malt is hoisted to the top floor where it may be screened and graded. From there it is then conveyed to the malt mill usually by way of an automatic weighing machine. Modern malt mills are designed not to grind the malt to flour, but to separate the internal part of the grain as completely as possible from the husks, grind it no finer than is necessary for complete extraction in the mash-tun and mix the "grits" and meal with the husks in a homogeneous "grist."

The grist, with which any flaked material used is intimately blended, passes to the "grist-case" and thence to the "mashing-machine" in which it is mixed with hot water of nicely adjusted temperature, drawn from the "hot liquor tank." From the mashing machine the thick mash of malt and water flows to the "mash-tun." This vessel is usually constructed of wood, iron or copper and is placed in most cases directly under the mashing machine above which is located the conical bottom of the grist-case. Inside the tun is a sparging apparatus consisting of pipes which are caused to rotate by the flow of water through fine holes in their sides. The water sprays every part of the "goods" in the tun and washes the wort from them after mashing is completed. The mash-tun has a gun-metal or bronze false bottom pierced with slots or holes designed to hold back the "grains" while the wort is running from them through "spend pipes" in the bottom to the "taps." It is also filled with rakes mechanically driven round in the mash to ensure thorough admixture. They are omitted in some mash-tuns, reliance for mixture being placed on the mashing machine. In other plants, without mashing machines, they may be used to mix the grist and water in which case they are sometimes replaced or assisted by a "propeller." The mash-tun is lagged and covered, sometimes with a copper dome as in the figure which is from a photograph of the mash room in a modern brewery. There are means for raising the temperature of the mash by an "underlet" or inflow of hot liquor through the bottom and in many cases an elaborate installation of thermometers for temperature control. After mashing is completed the spent grains are removed usually through grains slides in the bottom of the tun.

The object of mashing is the production of "wort" containing suitable proportions of fermentable and unfermentable "extract" from the grist. The extract is derived partly from the soluble carbohydrate and nitrogenous constituents of the malt, but also in larger part by conversion of its starch into soluble substances. As the character of beer depends so largely on the amount and proportions of these in the wort, the mashing process is of fundamental importance and most carefully controlled. In the "Infusion mash" most commonly employed for top fermentation beer the "initial heat" or temperature of the completed mash usually varies from about 145° to 155° F between which temperatures the diastase of the malt is still active, and at which the modified starch of the malt is brought into a suitable condition for its converting action. These temperatures are rather too high for much proteoclastic, or protein digesting action to take place and this has largely been assured by the system of malting adopted so that the wort shall contain, in addition to soluble carbohydrates derived from the starch, an adequate amount of dissolved nitrogenous substances. If high temperatures are employed they are maintained throughout the mash. If low initial temperatures are adopted the heat is raised after about half an hour by about 5 degrees, generally by an "underlet" of hot water, more easily and fully to convert any "steely" ends or unmodified starch in the malt. After a rest of about 1 to 1½ hour the wort is run off and the grains extracted as completely as possible by "sparging" on water of rather higher temperature than that of the mash. After the wort is drained from the mash-tun, the "grains" are removed and form a valuable cattle food (*q.v.*).

The chemistry of the changes which take place in the mash-tun is extraordinarily complex and is not yet fully understood. It consists essentially of the conversion of insoluble colloid constituents of the grain, of which starch forms the major part, into soluble substances. The starch and proteins of the grain have both been "modified" during malting (*q.v.*): the starch in such a way as to render it more readily amenable to the action of the

diastase of the malt. It is generally recognized that at least two enzymes are included in the term diastase. Broadly speaking, it may be said that the chief products of the saccharification of starch are the fermentable sugar, maltose, and unfermentable dextrin; but there are other potentially fermentable substances of more complex molecular structure than maltose but less complex than dextrin, among which two malto-dextrins have been characterized. These substances are dissolved in the wort and their relative proportions vary with the conditions in the mash-tun, largely as the latter influence the energy of the diastatic action or conversion. Among these influences are the restricting effect of higher temperatures and alkaline salts in the water on the one hand, and the accelerating effects of slight acidity, dilution, etc., on the other. These with the nature of the grist, in regard to its diastatic power, modification and character of the malt and proportion of raw or prepared grain determine the nature of the wort and ultimately of the beer. Very careful co-ordination of malting and mashing processes are therefore demanded. Restriction of diastase, consequent on high kilning heats, can to some extent be counterbalanced by low mashing heats, while higher mashing heats, and those used in the sparge, can be used to bring undermodified malt into a condition suitable for conversion, providing the saccharifying power of the malt is sufficient and not unduly crippled by those high temperatures. The hydrolysis and solubilization of certain of the proteins of barley is as important as the conversion of the starch in brewing. The proteoclastic enzymes are however inhibited at considerably lower temperatures than those which prevent diastatic action and their activity in the usual infusion mash is very much restricted. Reliance must, therefore, be placed on the malting process for much of the necessary degradation. Temperatures of 100° to 110° are required to determine much proteoclastic change in the mash-tun and at times such digestive temperatures are adopted in the infusion system.

The result of these changes, in malting and mashing, is comparable to that undergone by starch and is the production from proteins of colloidal degradation products of high complexity, peptones, etc., and a greater or smaller amount of simpler nitrogen compounds of which the amino-acids and amides are typical. Malting barley may contain between 6.5 and 12% of proteins, on which, to a large extent, the flavour, etc., depend. Moreover, fermentation cannot go on satisfactorily without a sufficient proportion of assimilable nitrogen for the needs of the yeast. Excess in quantity or unsuitability in composition is harmful and leads to difficulty in fermentation and lack of brilliance in the beer.

When flaked cereals or raw grain are used in addition to malt, variations are made in the mashing process. The starch of flaked maize or rice is gelatinized during the process of flaking and is readily converted in the mash-tun by the diastase of the malt, and the only modification in process required is the careful mixture of the flakes with the grist. If unmalted grain is used in the form of "grits" its starch must be gelatinized before mixing with the malt which provides the diastase for its conversion. This is done by heating with water, sometimes in a "converter" under pressure at a temperature somewhat higher than the boiling point of water and sometimes in an open cooker between 190° and 212°. In either case a small amount of malt is usually mixed with the grain to assist gelatinization. The gelatinized grain is pumped into the mash-tun, where the main mash of malt has stood at least half an hour, care being taken that the temperature of the mixture is not above that suitable for the complete saccharification of the starch. Mash-tun rakes or propellers are used to mix the two mashes. It may be noted that the proteins of raw grain are not acted upon by the diastase of malt. Modern improvements in mashing plant and processes are designed to extract the largest quantity of desirable substances from the grist and to ensure fullest control of the conditions of temperature, etc., which influence conversion. Various processes other than that adopted in the mash-tun with false bottom have been suggested for separating the wort from the grains, among them centrifuges and filters. The latter in the form of filter presses with cloth filters have proved suitable and are used to a considerable extent in Continental Europe but have not been adopted to any

extent in England. It is claimed for the "Mash Filter" that a more complete extraction can be obtained with less washing liquor, and more quickly than with the mash-tun and sparge, but the trouble with the cloths, and the readiness with which the well-modified malts used are extracted has restricted their adoption in conjunction with the infusion mash.

**Boiling.**—From the mash-tun the wort passes to the coppers either by gravitation or through an intermediate vessel known as the "Underback" from which it is pumped up to the coppers. These are large open or closed vessels, almost always of copper, in which the wort is boiled with the hops either by direct fire or by steam in coils, jacket or tubular heater. Hops are added in quantity generally varying from  $\frac{1}{2}$  to 3 lb. per barrel according to the character of the beer, and the wort is boiled from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  hours. The objects of boiling may be summarized as follows: (1) Sterilization of the wort. (2) Extraction from the hops of the substances which give flavour and aroma to the beer and ensure its stability. (3) Coagulation and precipitation of that part of the proteins contained in the wort which, if left in, would later on gradually separate as a haze in the beer, spoiling its appearance and flavour. (4) Concentration of the wort. (5) Destruction of the enzymes.

The separation of the wort from the hops previous to cooling is a stage of considerable importance in that the insoluble substances separated in the copper must be removed as perfectly as possible. This is effected in most breweries in the "Hop back," a large iron or copper vessel with perforated false bottom to which the wort runs from the coppers. In it the hot wort is allowed to stand for a short time for the hops to settle down and form a filter bed through which the "hopped wort" is drawn off or pumped to the coolers or wort receiver. The hop back is fitted with a sparge to wash out wort otherwise retained in the "spent hops" which are afterwards used in the manufacture of cattle-foods and in manures.

**Cooling.**—In old breweries there was no means of cooling the wort other than by letting it lie in a shallow open vessel, known as a surface "cooler," exposed to the atmosphere in a room generally fitted with louvres. In some modern breweries these are still retained in the form of large shallow copper pans, but the wort is never allowed to cool down below  $150^{\circ}$  F to  $140^{\circ}$  F, at which temperatures micro-organisms deposited from the air would be rendered, to a great extent, harmless. In others, and no doubt the larger number, surface coolers have been entirely abolished and their place taken by smaller deep vessels known as "wort receivers" from which the wort passes to refrigerators. The advantage or otherwise of such coolers has been widely debated, but there is no doubt that a better clarification of the wort is obtained when they are retained. While the large surface of wort exposed in surface coolers greatly facilitates the deposition of colloidal matter which would otherwise impede fermentation and impair the brilliance of the beer, it entails liability to aerial infection. Recognition of the importance of surface in the deposition of colloids has led during recent years to the development of refrigerators, avoiding the danger of infection, yet spreading the wort over a large surface while rapidly cooling it. The two most commonly employed types of refrigerators consist of a series of pipes, arranged usually on a vertical frame or in a horizontal trough, through which cold water is circulated and over which the wort flows, its temperature at the outlet being reduced to about  $60^{\circ}$  or  $58^{\circ}$ . In modern breweries the refrigerators are usually erected in specially constructed rooms designed to avoid contamination from dust or dirt and into which only filtered air free from micro-organisms is allowed to enter. Recently there has been introduced a new form of enclosed refrigerator built in the manner of a filter press equipped with shallow compartments separated by copper plates. Through these the hot wort and cold water pass in opposite directions.

**Fermentation.**—The cooled wort is run to the "fermenting vessels" where yeast is added and the wort allowed to ferment until it becomes beer. Yeast (*q.v.*) is a unicellular vegetable micro-organism or fungus of which there are many species. That used in brewing is known as *Saccharomyces cerevisiae* and con-

sists of almost spherical cells about  $\frac{1}{8,000}$  of an inch in diameter. During fermentation these cells increase in number by budding, deriving their nutriment from the wort and breaking down the sugars contained in the latter into almost equal parts of alcohol and carbonic acid gas. As added to the fermenting vessels the yeast or barm is a liquid mass of creamy consistency. During the earlier stages of fermentation there is a great evolution of carbonic acid gas. At a later stage the yeast, increased three to five-fold by its vegetative growth, rises to the top of the vessels in top fermentation, and is removed and used again for succeeding brews. The excess over that required for this purpose is pressed and in some breweries pressed yeast is used for "pitching." The ale filtered from it is returned to the fermenting vessels while the pressed yeast is sold to distillers or used for making cattle foods or yeast extracts for human consumption. Very little is now used for baking as it is not so satisfactory for that purpose as specially prepared baker's yeast (*q.v.*).

There are several systems of fermentation employed in top-fermentation breweries, differing in the construction of the vessels in which the process is carried out and in the means adopted to separate the yeast from the beer. It is of interest to examine the ancient brewery of Queen's college, Oxford, to gain an idea of the manner in which these systems have developed. There are few, if any, breweries remaining in the country of equal antiquity to that at Queen's and probably the process carried out is the same as that which has prevailed for hundreds of years, with very few modifications, such as the adoption of thermometers. The mash-tun has no false bottom. The wort is pumped to the copper by means of a 16th century lead and wood hand pump, is run down a wooden trough to the surface cooler, where it remains for several hours. There is no refrigerator but a recent addition is a copper coil in one of the surface coolers to hasten cooling. The wort at  $66^{\circ}$  then runs to a wooden fermenting round, where the yeast is added and in which there is no means of controlling the temperature. There it remains for a night and a day while fermentation progresses. When this process slackens the yeast begins to come to the surface of the wort and the cleansing stage follows, during which the new yeast is removed. In this old system, still employed in many old small top-fermentation breweries in northern France, the cleansing takes place in casks. In this particular brewery, there is no means of running the wort out of the fermenting vessel, and it is ladled into the casks through a "tun-bowl" placed in the bung-hole. The casks after filling are rolled to a cellar and there set up over a wooden trough with their bung-holes open. Through these the yeast works out, together with beer, and runs over the sides of the casks into the trough, from which the beer is returned to the casks. When fermentation is completed the casks are filled up from a cask specially retained for that purpose and, after settling, the beer is transferred to storage casks or allowed to remain in the cleansing cask until bright and ready to drink.

**Burton Union System.**—The above old process of fermentation has developed through the Ponto system to the celebrated system so largely adopted at Burton-on-Trent, but at very few other places. In this "Union" system the wort is first fermented for about 36 hours in fermenting vessels typically of about 50-barrel capacity, from which it is run or pumped to the sets of union casks. Two fermenting vessels usually fill one "set." These union sets consist of a number of casks of three- or four-barrel capacity connected together by means of copper pipes and each fitted with a small "attemperator" for controlling the temperature, which always rises during fermentation. A copper "swan-neck" is fixed in the bung-hole of each cask, and through this the yeast working out from the cask passes into the "barm-back" running above the whole length of the set. Another trough, known as the "feeder" is constructed at the end of, and transverse to, the barm-back. The beer which separates from the yeast in the barm-back runs into this and is periodically run back into the casks, which are thus kept full. The cleansing takes about five days. The beer is then run from the casks to the racking or settling backs and thence to the trade casks. This system assures an excellent separation of the yeast from the beer and leaves the yeast finally in the

barm-back in a very good condition for pitching succeeding brews. The large number of small vessels however entails a considerable amount of waste and the sets require a great deal of attention and cleaning. For this reason simpler systems are more frequently used. In a modern development of the "Union" system of fermentation, the large number of casks in a "set" have been replaced by two aluminium tanks, and the backs are also made of aluminium.

**The Skimming and Dropping Systems.**—In the "Skimming" system, fermentation is carried right through to the end in one single vessel. The vessels in this system may be very much larger than those employed in the first part of the union system. Vessels holding several hundred barrels are common. Fermentation takes about five days or a week. The yeast is skimmed off through a slide in the side of the vessel or down a parachute, that delivers it directly into a "yeast back." These fermenting vessels are always fitted with attemperators. In the "Dropping" system the wort is removed from the fermenting to a cleansing vessel when the gravity has fallen to one half of the original gravity. In the second vessel, the removal of the yeast is carried on just as in the skimming system, being removed through a slide in the side of the vessel or down a parachute. At the close of fermentation, a thin covering of yeast is always left to protect the beer from aerial infection.

**Materials Used for Vessels.**—Many materials are used in the construction of fermenting vessels the main points in their selection, apart from cost and mechanical considerations, being the ease with which they can be kept clean and sterile and their freedom from any action on the beer. Wood of many kinds is employed, oak, kauri pine, red deal, cedar, etc.; but of recent years the tendency has been to use copper or aluminium. Glass-lined or enamelled steel vessels and cement or ferro-concrete tanks are also largely used. Cement vessels are lined with some smooth-surfaced resistant enamel. They are convenient in that they may form part of the constructional details of the room.

**Yorkshire Stone Square System.**—Stone or slate vessels are used in this system, which is only found in the north of England. The system differs from the others in that fermentation is carried out in a covered slate vessel with a man-hole in the centre of the cover through which the yeast works out into an upper back from which the beer separating from the yeast runs back through a pipe into the lower vessel. Temperature is controlled by a jacket containing water or by movable attemperators. A typical feature is the periodical pumping to which the wort is subjected during fermentation.

Fermenting vessels are now frequently constructed so that, after excise regulations are complied with and the charge is taken, they can be completely closed or covered with a dome in order that the carbon dioxide evolved during fermentation may be collected. The gas is pumped off and stored in large containers usually at a pressure of about 250lb. per sq.in. for use in the brewery itself or the bottling. The gas collected in this way, containing over 99.8% of carbon dioxide is valuable for carbonating bottled beer. Large quantities of fermentation gas are also liquefied and sold to mineral water factories.

Among the most important technical improvements of recent years are those connected with the purity of the yeast and its suitability for pitching. Many breweries are fitted with yeast backs frequently of slate, beneath the fermenting vessels. In the dropping system they form the lowest of the three floors of vessels. In these the yeast is drained of the accompanying barm-ale. They are, however, more or less exposed to contamination and frequently movable receivers are used in which all yeast required for pitching is removed to a room designed to be kept scrupulously clean and at a suitably low temperature. The Scott system is a development of this. The yeast is removed from the fermenting vessel by gravity or suction to closed aluminium tanks on wheeled carriages or run-ways. From these the yeast is forced by compressed air through filter presses and separated from the barm-ale. By this system, the yeast is kept from atmospheric contamination; and the accompanying beer is rapidly separated and returned to the fermenting vessels.

**Racking.**—Racking is the final stage of filling the trade casks. It is usually carried out with racking machines which minimize the loss of beer and carbon dioxide and completely fill the casks. Many beers are dry hopped, that is to say from 2oz. to a pound of specially selected hops are placed in the casks previous to racking to give additional hop aroma to the beer. In order to bring the beer more rapidly into condition "primings" are also frequently added. These consist of sugar solutions of a gravity of about 1.140, between a pint or a gallon being usually added. This quickly ferments and gives the beer a good condition. In certain cases, particularly with stout in Ireland, fermenting wort is added instead of sugar priming to give the very high condition demanded. Stock ales are finally given a period in store for maturation before sale, some strong ales quite lengthy periods, up to a year. Most beers are, however, sold after a few days or weeks. With the quick sale demanded of modern light ales the brilliance produced by long storage is replaced by a rapid system of fining. The finings separate from the beer, removing all matters in suspension and leaving the beer brilliant.

**Lager Brewing.**—To a large extent lager beer has superseded top-fermentation ales on the European Continent and in most countries other than the British Isles. The broad distinctions between the two systems have been mentioned. In the typical German system no sugar or raw grain was used; although of late years these have been coming more and more into use. In the bottom-fermentation process developed in America, raw grain, usually maize or rice grits, was largely used. Briefly described the course of operations in the classical German system is as follows: A "decoction mash" is used instead of the infusion mash previously described. A typical installation would be of two or three copper vessels. In the first, the mash is made at about 100° at which temperature the proteolytic enzymes are active and peptonization of the proteins of the malt takes place. About one-third of the "thickmash" is run to the "mash kettle" and there gradually raised to boiling point and boiled for a short time. It is returned to the mash which is thereby raised in temperature to 122°–126°. A second thick mash is similarly gradually raised to boiling and returned, raising the temperature of the main mash to 145°–150°. A third mash, usually a "*Lautermasch*" or "clear mash" is run to the kettle; raised to boiling point and returned, thus raising the temperature of the complete mash to about 167°. The running off of the wort and boiling with hops is very much the same as in the infusion mash, though the amount of hops used is generally somewhat less. The general appearance of a lager brewhouse is distinctive with its copper vessels surmounted by domes and chimneys to carry off the steam. The brewhouses or "Sudhaus" of large German breweries generally are equipped with a duplicate plant of three vessels. The mash is made in the front vessel, boiled in the central kettle and the wort drawn off from the grains in the mash-tun with false bottom and sparge to which the whole mash is finally pumped, and in which it is allowed to settle.

Fermentation is carried out in cellars maintained at a low temperature by refrigerating machinery with brine or direct expansion coils or by a current of cold air. The wort is pitched at temperatures varying between 41° and 50° rising during fermentation, which takes a period of 9 to 12 days, some five degrees above these temperatures and being finally cooled to between 36° and 45° before transference to the storage or "lager" casks. The yeast employed falls to the bottom of the fermenting vessels instead of rising to the top. The lager casks used to be made of wood, and varied in capacity from 20 to 50 barrels, but glass lined steel tanks, and sometimes cement tanks, of several hundred barrel capacity are now replacing the old wooden casks. These are arranged in cellars maintained close to the freezing temperature and the beer is kept there for periods varying from a few weeks to several months. "*Kräusen*" or fermenting wort is sometimes blended with the stored beer to increase the condition. Deposition of yeast and proteins takes place in the lager casks and, owing to the slow fermentation which goes on therein and the greater solubility of carbonic acid gas at low temperatures, the beer develops a very fine creamy condition. After storage it is

filtered to the trade casks. Lager beers of similar gravity to English beers are usually fermented to a less extent and consequently contain somewhat less alcohol and more unfermented extract. They are less heavily hopped and more highly charged with carbonic acid gas. The beer in cask must be kept cold and served rapidly. Top-fermentation beers are typically more stable on account of the larger alcohol content and greater hop rate.

**Types of Lager Beer.**—In Continental Europe several brewing centres have become celebrated for distinct types of lager beer, of which three may be specially mentioned. These are the dark, sweet, full-flavoured Munich beer, the pale, delicately hopped drier beer for which Pilsen is famous, and a medium pale type represented by that of Vienna. The Dortmund beer is another type of pale lager, with less pronounced hop flavour than that of Pilsen. Typically they vary in strength between  $12\frac{1}{2}$  to  $14\frac{1}{2}$  degrees Balling, equivalent to 1,050 to 1,058 specific gravity. These type names, together with others derived from brewing centres such as Budweiss or Wurtzburg, are frequently applied to corresponding beers brewed elsewhere.

A strong lager beer of 1,057 original specific gravity, or 14 degrees Balling, would contain on an average about 6% of residual extract and 4% of alcohol; lighter lagers brewed at 10 or 12 degrees Balling, correspondingly less.

Many modifications of the typical German "lager" system have been developed, largely in America, and are used elsewhere. Where maize or rice are available and permitted, they are used in the form of flakes or grits in varying proportions, from 10 to 40%, with the malt. Saturation with carbonic acid gas, largely derived from the fermenting wort itself, has in many places taken the place of krausen for producing the condition required. Somewhat higher fermenting temperatures, with a correspondingly shorter time in fermenting vessels, were frequently used in America than is customary in the German breweries.

The sale of lager beer in bottle has greatly increased of recent years. In the large breweries in Copenhagen over 95% of the output is bottled in magnificently organized bottling halls fitted with automatic machinery. In order to ensure purity and stability, an increasing proportion of bottled lager beer is pasteurized, particularly for export and consumption in hot countries.

**Pure Yeast.**—Among the greatest advances in brewing of recent years has been the introduction and use of pure yeast. Pasteur showed that many of the diseases of beer were caused by bacteria and, later, Hansen proved that others were due to the presence of varieties of yeast other than the normal brewing yeast. This naturally resulted in endeavours to obtain yeast which should be free from these organisms. Hansen's method of producing a mass of yeast from one single cell, selected because it was of desirable type, was first adopted on a large scale in the Old Carlsberg brewery in 1881, and is now very frequently installed in lager breweries. Sufficient culture yeast of strict biological purity is grown up in this apparatus to pitch the brewery fermenting vessels and the use of pure yeast results in greater certainty and regularity of produce. It has not hitherto been found possible to make use of pure yeast in top-fermentation breweries largely on account of the secondary fermentation required for some beers and carried out in the cask before sale and on which the characteristic flavour of the beer depends. The secondary fermentation is largely brought about by other varieties of yeast. To-day secondary fermentation is sometimes eliminated and it is possible that pure yeast may be adopted in time in top-fermentation beers also.

**Spontaneous Fermentation.**—There is no doubt that beer was first made by yeast which found its way accidentally into the wort, just as wine is to-day produced through the agency of yeast occurring on the skin of the grapes. Even at the present time a large amount of beer is made in various countries on this plan. *Lambic* and *Faro* are well known and appreciated in Belgium. The wort for these beers is made in a similar way to that for other beers but when cooled it is run into casks for fermentation. No yeast is added and fermentation commences spontaneously. It is brewed in the winter. Fermentation gradually increases and then stops to commence again as summer comes. It may then

be kept a couple of years before use. The organisms which gain access to the cask, producing fermentations of this kind, are very varied. There are yeasts of many kinds, and in addition bacteria producing the acidity which is liked. *Weissbier*, made in Berlin, is another beer in which the presence of lactic acid bacilli is necessary to produce the desired acidity. It is usually prepared from a mash consisting of three parts of wheat malt and one of barley malt. The yeast used contains the bacillus. In England, it was formerly customary to vat beer and stout for periods of a year or more, during which time a development of lactic acid took place. Very little old beer of this type is now brewed though the taste for it still persists in the West Country and some is made in Bristol. The power possessed by certain micro-organisms of converting starch to sugar and subsequently of fermenting the sugar is made use of in the preparation of the Japanese beer known as *saké*. The basis of this beer is steamed rice, the starch of which is converted to sugar by a culture of *Aspergillus oryzae*. The *koji* thus produced is added to a thin paste of fresh boiled starch in a vat. This is called *moto*. Fermentation is set up and lasts 30 to 40 days. More rice and *koji*, together with water, is then added to the *moto* and a secondary fermentation lasting eight or ten days ensues. The whole is finally heated, filtered and run into casks as *saké*.

### BEER BOTTLING

There are two main methods of bottling beer. In the first, the older and simpler method, the beer is at a certain age after casking merely run into a bottle, stoppered and stored. During storage a slight fermentation takes place in the bottle and these beers have a sediment due to the yeast thus formed. These are called "naturally conditioned beers." In the second method, beer in bulk is surcharged with carbonic acid gas and filtered into bottle, so that there is no sediment. These are the so-called non-deposit beers; this latter class now forms the majority of bottled beer.

**Naturally Conditioned Beers.**—Naturally conditioned beers form the higher class of pale ales and stouts. The beer is matured in cask before bottling, and this, with the subsequent fermentation in bottle, produces a character which is frequently absent from the non-deposit beers. The production of these beers requires more technical skill in obtaining just the right quantity of gas in the beer as sold. They require more careful pouring out and there is a certain amount of waste. These points militate against their popularity.

**Non-deposit Beers.**—The methods of treating the beer before filtering in order to surcharge it with carbonic acid gas vary widely, but most methods involve chilling the beer to a low point. The three methods most practised are as follows: (1) The beer is run into a tank where wort or sugar solution (priming) is added; the tanks are then sealed so that the gas formed by fermentation of the sugar produces considerable pressure; the beer is then transferred to other tanks in a cold room, where it can be chilled to about  $30^{\circ}$  to  $32^{\circ}$ , when matter of a proteid nature comes out of solution and most of the carbonic acid gas is entirely dissolved. The beer is then forced, either by means of air or carbonic acid gas pressure or pumps, through a filter of pulp of cotton fibre straight into a bottle filling machine. (2) Instead of forming the carbonic acid gas by fermentation, the beer is chilled and the gas is introduced artificially and mixed with it under pressure; the beer is then stored for a period of varying length before being passed through the filter and bottled. (3) In this method, the beer is brought to a low temperature rapidly through a tubular or other form of cooler, carbonated, and filtered and bottled at once. There are many variations in details of these methods, but the general opinion is that conditioning in tank by fermentation and long storage after chilling gives rather a better flavour and the beer remains longer in bottle without throwing any deposit.

**Bottling Machines.**—The filling of bottles readily lends itself to mechanical contrivances and automatic bottling units in which hundreds of bottles per hour can be dealt with are quite common. The unit consists of soaker, rinser, filler, crowner or corker and labeller all carefully synchronized (*see fig. 7*). The washing of bottles is of great importance as they should be sterile before filling. In modern soaking machines the bottles are passed through solutions

DIAGRAMMATIC VIEW OF AUTOMATIC BOTTLING PLANT, SHOWING, FROM LEFT TO RIGHT, THE CONTINUOUS PROCESS BY WHICH BOTTLES ARE CLEANED, FILLED, CORKED AND LABELLED, WITHOUT BEING TOUCHED BY HAND. BY PERMISSION OF WHITBREAD & CO.

of caustic soda of different temperature, say,  $90^{\circ}$  and  $120^{\circ}$ , then passed through warm water and finally cold water before being delivered on to the conveyor. They may or may not be brushed externally and internally by revolving brushes. In some washing machines, the bottles are carried on endless chains and submitted to rinsing by powerful jets, inside and out, of hot caustic soda solution and finally warm and cold rinsing waters. The conveyor then carries them under the filling machine. The usual filling machine is rotary in form and has from 12 to 36 filling heads attached to a beer container at the top, which is kept automatically full and under pressure. As a bottle comes under a head it is raised into position, thereby turning on the beer, and when full the beer is automatically shut off and the bottle returned to the chain conveyor. The bottle is then carried along to the stoppering machine. If crowns or corks are used, mechanical apparatus can deal most efficiently with the stoppering, but if screw-stoppers are employed, they must be inserted by hand. At present, crowns are the commonest form of stoppering; corks are daily becoming more rare; but screws are still holding their own for pints and quarts, because of the convenience of re-stoppering half-empty bottles by the consumer. After stoppering, the bottle is conveyed to the labeller; although there are many automatic labellers in use, some brewers still prefer to label by hand.

The lay-out of the bottling plant has to be very skilfully arranged to keep down the number of operators required: three operators for a 120 dozen per hour unit and six for a 500 dozen unit is the minimum that can be attained.

The pasteurizing of bottled beer is common on the Continent with lager, but it is not practised in England to so great an extent; it is, however, gradually coming in. Where it is used the pasteurizer is connected up with the bottling unit between the crowner and labeller. The pasteurizing process consists of heating the bottled goods up to  $140^{\circ}$  to  $150^{\circ}$  for 20 minutes and the process has to be gradual to avoid undue breakage. The simplest form of pasteurizer is a shallow tank of water with a false bottom and heated by steam coils, but tanks in series of increasing temperatures are used, and also sheet-iron cabinets in which the bottled goods are placed on trays and then submitted to heavy spraying with water gradually heated to the temperature desired.

The tanks used for conditioning and chilling beer are made of glass-lined steel, copper, aluminium or even iron coated with spirit enamel. The first named is the favourite, but when beer is chilled rapidly and in comparatively small quantities, copper is the favourite material. For carbonating, many brewers use the gas collected from their own fermentations which is brought under pressure in large containers made of boiler plate; others buy the gas liquefied in tubes.

**BREWSTER, SIR DAVID** (1781–1868), Scottish physicist, and one of the founders of the British Association, was born at Jedburgh on Dec. 11, 1781, and died on Feb. 10, 1868, at Allerby, Melrose. He made his name by a series of investigations on the diffraction of light, the results of which he contributed from time to time to *Philosophical Transactions* and other scientific journals.

The most important subjects of his enquiries are enumerated by J. D. Forbes, in his preliminary dissertation to the 8th ed. of the *Encyclopædia Britannica*, under the following five heads: (1) The laws of polarization by reflection and refraction, and other quantitative laws of phenomena; (2) the discovery of the polarizing structure induced by heat and pressure; (3) the discovery of crystals with two axes of double refraction, and many of the laws of their phenomena, including the connection of optical structure and crystalline forms; (4) the laws of metallic reflection; (5) experiments on the absorption of light. In this investigation the prime importance belongs to the discovery (1) of the connection between the refractive index and the polarizing angle, (2) of biaxial crystals, and (3) of the production of double refraction by irregular heating.

Brewster was elected F.R.S. in 1815, and was awarded the Rumford gold and silver medal for his discoveries in connection with the polarization of light in 1818. He did not invent the kaleidoscope, but he may be said to have rediscovered it. He improved the stereoscope by suggesting the use of lenses to combine the dissimilar binocular pictures. More important was his work in persuading the British authorities to adopt the dioptric apparatus, perfected by Fresnel, in their lighthouses. He suggested its use for this purpose as early as 1820. Brewster was one of the group of scientific men who assembled in the archiepiscopal palace at York and developed the idea of a British Association for the Advancement of Science, realized in 1831. (See LEARNED SOCIETIES.) In 1838 Brewster became principal of the united colleges of St. Salvator and St. Leonard, St. Andrews, Scotland, and from 1859 till a short time before his death was principal of Edinburgh university. In 1849 he had the honour of succeeding J. J. Berzelius as one of the eight "foreign associates" of the Institute of France.

In spite of his activity in research and, in his later days, in university life, Brewster accomplished a mass of literary work. He edited the *Edinburgh Encyclopædia* (1808–30), was one of the leading contributors to the 7th and 8th editions of the *Encyclopædia Britannica*, joint editor (1819–24) of the *Edinburgh Philosophic Journal*, and then (1824–32) editor of the *Edinburgh Journal of Science*. Among his many separate publications may be mentioned his *Treatise on Optics* (1831) and his *Memoirs of the Life, Writings and Discoveries of Sir Isaac Newton* (1855).

See *Home Life of Brewster* (1869) by his daughter, Mrs. Gordon; Ostwald's *Klassiker der exacten Wissenschaften*, No. 168 (Leipzig, 1908).

**BREWSTER WILLIAM** (c. 1566–1644), American colonist, one of the leaders of the "Pilgrims," was born at Scrooby, Notts, England, c. 1566. After studying for a time at Cambridge,

he was from 1584 to 1587 in the service of William Davison (?1541-1608), who in 1585 went to the Low Countries to negotiate an alliance with the States General and in 1586 became assistant to Walsingham, Queen Elizabeth's secretary of State. Upon the disgrace of Davison, Brewster removed to Scrooby, where from 1590 until Sept. 1607 he held the position of "Post," or postmaster responsible for the relays of horses on the post road. About 1602 his neighbours began to assemble for worship at his home, the Scrooby manor house, and in 1606 he joined them in organizing the Separatist Church of Scrooby. After an unsuccessful attempt in 1607 (for which he was imprisoned for a short time), he, with other Separatists, removed to Holland in 1608 to obtain greater freedom of worship. At Leiden in 1609 he was chosen ruling elder of the Congregation. In Holland he supported himself first by teaching English and afterwards in 1616-19, as the partner of one Thomas Brewer, by secretly printing, for sale in England, books proscribed by the English Government, thus, says Bradford, having "impoyment enough." In 1619 their types were seized and Brewer was arrested by the authorities of the University of Leiden, acting on the instance of the British ambassador, Sir Dudley Carleton. Brewster, however, escaped, and in the same year, with Robert Cushman (c. 1580-1625), obtained in London, on behalf of his associates, a land patent from the Virginia company. In 1620 he emigrated to America on the "Mayflower," and was one of the founders of the Plymouth Colony. Here besides continuing until his death to act as ruling elder, he was also—regularly until the arrival of the first pastor, Ralph Smith (d. 1661), in 1629 and irregularly afterward—a "teacher," preaching "both powerfully and profitably to ye great contentment of ye hearers and their comfortable edification." By many he is regarded as pre-eminently the leader of the "Pilgrims." He died, probably on April 10, 1644.

Chamberlain, "William Brewster, the Pilgrim Printer," *Magazine of History*, vol. xv., p. 63-66 (1912); and Edward B. Pollard, "Elder Brewster, Lay Preacher of the Pilgrims," *Homiletic Review*, vol. lxxx., p. 264-268 (1920).

**BRÉZÉ**, the name of an Angevin noble family, the most famous member of which was PIERRE DE BRÉZÉ (? 1410-1465), one of the trusted soldiers and statesmen of Charles VII. He had made his name as a soldier in the English wars, and during the Praguerie he supported the royal cause against the dauphin Louis and the revolted nobles, a service which was remembered against him after Louis's accession to the throne. He fought against the English in Normandy in 1440-41, and in Guienne in 1442. He became chamberlain to Charles VII., and gained the chief power in the State through the influence of Agnes Sorel. The six years (1444-50) of his ascendancy were the most prosperous period of the reign of Charles VII. The dauphin Louis in 1448 brought against him accusations which led to a formal trial, resulting in a complete exoneration of Brézé and his restoration to favour. He fought in Normandy in 1450-51, and became seneschal of the province after the death of Agnes Sorel and the consequent decline of his influence at court. He made an ineffective descent on the English coast at Sandwich in 1457, and was preparing an expedition in favour of Margaret of Anjou when the accession of Louis XI. brought him disgrace and a short imprisonment. In 1462 he accompanied Margaret to Scotland with a force of 2,000 men, and after the battle of Hexham he brought her back to Flanders. He was reappointed seneschal of Normandy, and fell in the battle of Montlhéry, July 16, 1465. He was succeeded as seneschal by his eldest son Jacques de Brézé (c. 1440-90), count of Mauvielrier; and by his grandson, husband of the famous Diane de Poitiers, Louis de Brézé (d. 1531).

The lordship of Brézé passed eventually to Claire Clémence de Maillé, princess of Condé, by whom it was sold to Thomas Dreux, who took the name of Dreux Brézé, when it was erected into a marquisate. HENRI EVRARD (1762-1829), marquis de Dreux-Brézé, succeeded his father as master of the ceremonies to Louis XVI. in 1781. On the meeting of the states-general in 1789 it fell

to him to regulate the questions of etiquette and precedence between the three estates. Brézé did not formally intimate to President Bailly the proclamation of the royal séance until June 20, when the carpenters were about to enter the hall to prepare for the event, thus provoking the session in the tennis court. After the royal séance Brézé was sent to reiterate Louis's orders that the estates should meet separately, when Mirabeau replied that the hall could not be cleared except by force. After the fall of the Tuileries Brézé emigrated for a short time. At the restoration he was made a peer of France, and resumed his functions as guardian of an antiquated ceremonial. He died on Jan. 27, 1829, when he was succeeded in the peerage and at court by his son Scipion (1793-1845).

The best contemporary account of Pierre de Brézé is given in the *Chroniques* of the Burgundian chronicler, Georges Chastellain, who had been his secretary. Chastellain addressed a *Déprécation* to Louis XI. on his behalf at the time of his disgrace.

**BŘEZINA, OTTOKAR:** see JEBAVY, VÁCLAV.

**BRIALMONT, HENRI ALEXIS** (1821-1903), Belgian general and military engineer, son of General Laurent Mathieu Brialmont (d. 1885), was born at Venlo, Limburg, on May 25 1821. Educated at the Brussels military school, he entered the army as sub-lieutenant of engineers in 1843, and became lieutenant in 1847. From 1847 to 1850 he was private secretary to the war minister, General Baron Chazal. In 1855 he entered the staff corps, and became major-general in 1874. He was then made director of fortifications in the Antwerp district and in 1875 he became inspector-general of fortifications and of the corps of engineers. In 1883 he went to Rumania to advise on fortifications and at the request of the Hellenic Government prepared a scheme for the defence of Greece. He retired in 1886, but continued to supervise the Rumanian defences. He died on Sept. 21, 1903.

At first Brialmont's plans followed with but slight modification the ideas of Vauban, and his original scheme for fortifying Antwerp provided for both enceinte and forts being on a bastioned trace. But in 1859, when the great entrenched camp at Antwerp was finally taken in hand, he had already gone over to the school of polygonal fortification and the ideas of Montalembert. About 20 years later Brialmont's own types and plans began to stand out amidst the general confusion of ideas on fortification which naturally resulted from the introduction of long-range guns and from the events of 1870-71. The extreme detached forts of the Antwerp region and the fortifications on the Meuse at Liège and Namur were constructed in accordance with Brialmont's final principles, viz., the lavish use of armour to protect the artillery inside the forts, the suppression of all artillery positions open to overhead fire, and the multiplication of intermediate batteries (see FORTIFICATION AND SIEGE CRAFT). In his capacity of inspector-general Brialmont drafted and carried out the whole scheme for the defences of Belgium.

His most important publications were *La Fortification du temps présent* (1885); *Influence du tir plongeant et des obus-torpilles sur la fortification* (1888); *Les Régions fortifiées* (1890); *La Défense des états et la fortification à la fin du XIX<sup>e</sup> siècle* (1895); *Progrès de la défense des états et de la fortification permanente depuis Vauban* (1898).

**BRIAN** (926-1014), king of Ireland, known as BRIAN BORU, BOROMA, or BOROMHE (from *boroma*, an Irish word for tribute), was a son of a certain Cenneide, a chieftain of Munster. He passed his youth in fighting against the Danes, who were constantly ravaging Munster. In 976 his brother, Mathgamhain, who had become king of Thomond about 951 and afterwards king of Munster, was murdered; Brian avenged this deed, himself becoming king of Munster in 978. He forced the tribes of Munster and then those of Leinster to own his sovereignty, defeated the Danes, who were established around Dublin, in Wicklow, marched into Dublin, and after several reverses compelled Maelsechlainn, the chief king of Ireland, who ruled in Meath, to bow before him in 1002. Connaught was his next objective. Here and also in Ulster he was successful, everywhere he received hostages and tribute, and he was generally recognized as the *ardri*, or chief king of Ireland. In 1013 Brian was again at war with the Danes of Dublin, and on April 23, 1014, his forces gained a great victory

over them at Clontarf. After this battle, however, the old king was slain in his tent, and was buried at Armagh. One of his charters is still preserved in Trinity college, Dublin.

See E. A. D'Alton, *History of Ireland* (1903), vol. i.

**BRIANÇON**, a strongly fortified town and climatic resort in the department of Hautes-Alpes, south-east France, near the Italian frontier. Pop. (1926) 2,785.

The old town, composed of steep narrow streets, lies on a plateau over 4,000ft. high, above the upper Durance, at the foot of the descent from the Mont Genève pass (q.v.), 51m. by rail from Gap. Briançon, the *Brigantium* of the Romans, formed part of the kingdom of King Cottius. About 1040 it fell to the counts of Albon (later dauphins of the Viennois) and thenceforth shared the fate of the Dauphiné. The Briançonnais included the upper valley of the Durance and tributaries, and the valleys of the Dora Riparia and the Chisone on the eastern side of the Alps. By the Treaty of Utrecht (1713) these valleys were handed to Savoy in exchange for that of Barcelonnette, on the west slope of the Alps. In 1815 Briançon withstood a siege of three months at the hands of the allies, a feat commemorated by an inscription on one of its gates, *Le passé répond de l'avenir*. The modern town extends in the plain south-west of the plateau and forms the suburb of Ste. Catherine, with the railway station and an important silk-weaving factory. The conspicuous parish church dates from the 18th century. In summer Briançon is a busy tourist centre.

**BRIAND, ARISTIDE** (1862– ), French statesman, was born at Nantes March 28, 1862. As a law student he became associated with advanced movements in politics, writing articles for *Le Peuple*, and directing the *Lanterne* for some time. From this he passed to the *Petite République*, leaving it to found with Jean Jaurès, *L'Humanité*. At the congress of working men at Nantes in 1894 he secured the adoption of the general strike idea against the adherents of Jules Guesde. From that time, Briand became one of the leaders of the French Socialist party. In 1902, after several unsuccessful attempts, he was elected deputy. From the beginning of his career in the chamber of deputies, Briand was occupied with the question of the separation of Church and State. He was appointed *rapporteur* of the commission charged with the preparation of the law and succeeded in carrying his project through with but slight modifications, and without dividing the parties upon whose support he relied. He accepted the portfolio of public instruction and worship in the Sarrien ministry (1906) so that he might apply the law for which he was largely responsible. So far as the chamber was concerned his success was complete. But the acceptance of a portfolio in a bourgeois ministry led to his exclusion from the Unified Socialist party (March 1906). As opposed to Jaurès, he contended that the Socialists should co-operate actively with the Radicals in all matters of reform, and not stand aloof to await the complete fulfilment of their ideals. In Oct. 1906 Clemenceau formed his first government, and in it Briand remained minister of public instruction and worship. There were certain difficulties in the application of the Separation Law due to the hostility of the Vatican. It was then that Briand gave proof of his essential liberalism. Though he held fast to the principle of the new legislation, he made possible the carrying on of the rites of the Roman Catholic Church under the laws as to associations and public gatherings. On the death of Guyot-Dessaigne in Jan. 1908 he was appointed to the ministry of justice.

When the Government of Clemenceau fell in July 1909 Briand formed his first cabinet, himself taking the portfolio of interior and worship. He announced that he would adopt a policy of national understanding and tranquillity. In Oct. 1910 there was a threat of a general strike on the railways. Briand mobilized all the railwaymen who were still subject to military service, dismissed those who disobeyed and had the members of the strike committee arrested. A majority in the chamber approved his action, but in spite of this the Government resigned on Nov. 2, 1910, as a result of the withdrawal of Viviani, the minister of labour, who disagreed with his colleagues on the question of the right to strike.

Briand immediately formed a new cabinet, of a more radical tendency than its predecessor. This alteration, which offended the moderate Republicans without conciliating the Radicals, weakened

the position of the ministry. The parliamentary difficulties about the Franco-German agreement with regard to concessions in the Congo, which was one of the causes, or rather pretexts, of the Agadir crisis of the following July, was among the principal reasons for the resignation, some weeks later, of this Government, although this was not stated at the time. A parliamentary incident gave Briand an excuse for an unobtrusive withdrawal. In Feb. 1911, when he was accused by the Radicals of failing in the strict application of the law with regard to religious houses, his majority fell to six and he resigned.

After some months out of office, he became minister of justice in Poincaré's first cabinet on Jan. 13, 1912. When Poincaré was elected president of the republic in Jan. 1913, Briand succeeded him as premier. The life of this Government was brief. Its most important work was to ask parliament to lengthen the period of military service from two to three years as a rejoinder to the increase in German armaments. On March 18, 1913, on the question of electoral reform, the ministry was overthrown by the senate, which defeated a proposal already passed by the chamber to introduce proportional representation.

Briand remained more or less in retirement until the outbreak of the World War. On Aug. 26, 1914, Viviani felt himself obliged to broaden the base of his Government, and offered Briand the portfolio of justice. On the fall of the Viviani cabinet, Briand on Oct. 29, 1915, formed a government in which he himself took over the direction of foreign affairs. He made its character as a national coalition clear by including as ministers, without portfolio, the Socialist Guesde, the Catholic Conservative Cochin and the three former premiers, de Freycinet, Combes and Bourgeois. However, in the beginning of the summer of 1916, he was accused in certain political circles of a lack of vigour in the prosecution of the war.

By the end of autumn, the Rumanian disaster, and especially the situation in Greece, made him the object of further attacks. The question of the higher command was also causing much anxiety. At this time Joffre, who had been made a marshal, was replaced by Nivelle. Briand thought it advisable for all these reasons to reform his cabinet. He appointed Lyautey minister for war, and called in experts who were not in parliament to take charge of the more technical offices. On March 14, 1917, a difference of opinion between the chamber and Lyautey brought about the latter's resignation. After a vain attempt to reform his government, Briand decided to resign.

For three years Briand took scarcely any part in public affairs. It must, however, be noted that in Sept. 1917 von der Lancken, the civil commissioner of Germany in Brussels, renewing an attempt which he had already made in the spring, proposed to Briand, through a Belgian intermediary, a meeting in Switzerland to discuss the possibility of peace. Briand was inclined to accept the offer, but Ribot, the minister of foreign affairs, counselled him to avoid it as a snare.

During the years which immediately followed the war, Briand still remained in retirement. He showed, however, by one or two speeches in the chamber, that he was inclined to move to the Left. In Jan. 1921, on the fall of the Leygues ministry, he was called upon to form a government, and himself took charge of foreign affairs. He interested himself particularly in the application of the Treaty of Versailles, especially with regard to reparations. In the autumn he went to Washington as the French representative at the conference on naval disarmament. From that moment he was fiercely attacked by those who accused him of having failed to safeguard the interests of his own country. This campaign reached its height when, early in 1922, the Inter-Allied conference met at Cannes, and Briand discussed with Lloyd George the question of an Anglo-French defensive pact. A telegram which he received from Millerand, then president of the Republic, decided Briand to return to Paris and confront his enemies. When he arrived he realized that his position had become untenable. He announced his resignation to the chamber on Jan. 12, 1922.

In April 1925 he was offered the portfolio of foreign affairs in Painlevé's cabinet, and he remained in the same office in the second Government formed by this leader in October. The Locarno agreement in Oct. 1925 enormously increased the influence of Bri-

and, who had played an important part in the negotiations. When Painlevé resigned on Nov. 22, Briand became the new head of the Government.

On March 6, 1926, Briand's ministry fell, the chamber having thrown out a financial measure which he considered necessary. Briand, however, accepted office again, but the situation became more and more difficult because of the financial crisis and the continued depreciation of the franc. Raoul Péret, finance minister, suddenly resigned and the Government fell on June 15. But, once again, Briand reconstructed the ministry and brought in Caillaux as finance minister. A month later, on July 17, the ministry was defeated, the chamber refusing to grant the special powers demanded for dealing with the financial problem. Herriot's ministry, which succeeded it, lasted only a few days and fell on July 21. Poincaré then formed a coalition Government in which Briand again became minister for foreign affairs. In this position he continued to direct the foreign policy of France on the basis of European consolidation and reconstruction. He received the Nobel peace prize, at the same time as the two other principal signatories of the Locarno pact, Chamberlain and Stresemann.

A great parliamentarian, although he broke with the extreme Left in 1906, he retained his connection with many of the more advanced political thinkers. His genuinely liberal ideas, and his constant endeavours toward national unity, gained him the sympathy of the moderate parties. His ease and animation as a speaker, his parliamentary experience and his well-known ability in the conduct of foreign affairs, all contributed to that great influence which made him, up to that time, premier more often than any other politician in France. (*See OUTLAWRY OF WAR.*)

Briand's works include: *La Séparation des Églises et de l'État*, discussion of the new system (1909); *Paroles de Paix* (1927).

From July 27 to Oct. 22, 1929, he again served as premier.

(P. B.)

**BRIANZA**, a district of Lombardy, Italy, in the southern part of the province of Como, between the two southern arms of Lake Como. It is fertile, thickly peopled and visited in summer by Milanese who have built fine villas. There are silk, cotton-spinning, yarn and hat factories as well as a furniture industry.

*See* U. Nebbia, *La Brianza* (Arti Grafiche, Bergamo, 1912), well illustrated.

**BRIAREUS** or **AEGAEON**, in Greek mythology, one of the three hundred-armed, fifty-headed *Hecatoncheires* (Gr. *ἑκατόν, hundred, χεῖρες, hands, arms*), the sons of *Ouranos* and *Gaia* (Heaven and Earth). According to one legend, Briareus and his brothers were called by Zeus to his assistance, when Olympus was attacked by the Titans. The latter were defeated and thrown into Tartarus, the three brothers being set to guard them. Other accounts make Briareus an opponent of Zeus and one of the assailants of Olympus, who, after his defeat, was buried under Mount Aetna. Another tradition makes him a giant of the sea, an enemy of Poseidon and the inventor of warships. The *Hecatoncheires* may represent the gigantic forces of nature which appear in earthquakes and other convulsions, or the multitudinous motion of the sea waves, while Roscher sees in them a reference to the polypus, which often attained a great size.

**BRIBERY.** The offence of bribery may be defined as the offering, giving or accepting of consideration in some shape or form that it may be a motive in the performance of functions for which the proper motive ought to be a conscientious sense of duty. The offence may be divided into two great classes—the one where a person invested with power is induced by payment to use it unjustly; the other, where power is obtained by purchasing the suffrages of those who can impart it.

In England judicial corruption has been a crime of remarkable rarity. Indeed, with the exception of a statute of 1384 (repealed by the Statute Law Revision Act, 1881), there has been no legislation relating to judicial bribery. The first judicial scandal was that of 1289 when several of the judges were tried and convicted of corruption and other offences. The second was that of 1350 when Sir William Thorpe was fined and removed from office for accepting bribes. Other celebrated cases were those of Michael de la Pole, chancellor of England, in 1387; Lord Chan-

cellor Bacon in 1621; Lionel Cranfield, earl of Middlesex, in 1624; and Sir Thomas Parker, first earl of Macclesfield, in 1725. In Scotland for some years after the Revolution the bench was not without a suspicion of interested partiality; but since the beginning of the 19th century, at least, there has been in all parts of the empire a perfect reliance on its purity. The same may be said of the higher class of ministerial officers. There is no doubt that in the period from the Revolution to the end of Queen Anne's reign, when a speaker of the House of Commons was expelled for bribery, and the great Marlborough could not clear his character from pecuniary dishonesty, there was much corruption in the highest official quarters. The level of the offence of official bribery has gradually descended, until it has become an extremely rare thing for even the humbler officers to be charged with it.

In English law bribery of a privy councillor or a jurymen (*see* EMBRACERY) is punishable as a misdemeanour at common law, as is the giving or taking of a bribe by any judicial or ministerial officer. The buying and selling of public offices is also at common law and by statute the offence of bribery. By the Customs Consolidation Act, 1876, any officer in the customs service is liable to instant dismissal and a penalty of £500 for taking a bribe, and any person offering or promising a bribe or reward to an officer to neglect his duty or conceal or connive at any act by which the customs may be evaded shall forfeit the sum of £200. Under the Inland Revenue Regulations Act, 1890, the bribery of commissioners, collectors, officers or other persons employed in relation to the Inland Revenue involves a fine of £500. The Merchant Shipping Act, 1894, ss. 112 and 398, makes provision for certain offences in the nature of bribery. Bribery is, by the Extradition Act, 1906, an extraditable offence. Administrative corruption was dealt with in the Public Bodies' Corrupt Practices Act, 1889. The public bodies concerned are county councils, town or borough councils' boards, commissioners, select vestries and other bodies having local government, public health or poor law powers, and having for those purposes to administer rates raised under public general acts. The giving or receiving, promising, offering, soliciting or agreeing to receive any gift, fee, loan or advantage by any person as an inducement for any act or forbearance by a member, officer or servant of a public body in regard to the affairs of that body is made a misdemeanour in England and a crime and offence in Scotland. Prosecution under the act requires the consent of the attorney- or solicitor-general in England and of the lord advocate in Scotland. Conviction renders liable to imprisonment with or without hard labour for a term not exceeding two years, and to a fine not exceeding £500, in addition to or in lieu of imprisonment. The offender may also be ordered to pay to the public body concerned any bribe received by him; he may be adjudged incapable for seven years of holding public office, *i.e.*, the position of member, officer or servant of a public body; and if already an officer or servant, besides forfeiting his place, he is liable at the discretion of the court to forfeit his right to compensation or pension. On a second conviction he may be adjudged for ever incapable of holding public office, and for seven years incapable of being registered or of voting as a parliamentary elector, or as an elector of members of a public body. An offence under the act may be prosecuted and punished under any other act applicable thereto, or at common law; but no person is to be punished twice for the same offence. In certain cases penal servitude can be inflicted (*see* Prevention of Corruption Act, 1916, *infra*). Bribery at political elections was at common law punishable by indictment or information, but numerous statutes have been passed dealing with it as a "corrupt practice." In this sense the word is elastic in meaning and may embrace any method of corruptly influencing another for the purpose of securing his vote (*see* CORRUPT PRACTICES). Bribery at elections of fellows, scholars, officers and other persons in colleges, cathedral and collegiate churches, hospitals and other societies was prohibited in 1588-89 by statute (31 Eliz. c. 6). Bribery and corruption of and by agents and others is dealt with by the Prevention of Corruption Acts, 1906 and 1916. By the act of 1906 the giving or accepting of a bribe is made a misdemeanour punishable on indict-

ment by imprisonment not exceeding two years and—or—a fine not exceeding £500, on summary conviction the maximum penalties being four months and £50 respectively. A person serving under the Crown, or under a corporation or municipal or local council or board of guardians is an agent within the act, and the consent of a law officer is necessary for a prosecution. By the act of 1916 a person convicted on indictment under the Public Bodies' Corrupt Practices Act, 1889, or under the act of 1906, where the transaction had relation to a contract with the crown or public body, is liable to penal servitude not exceeding seven years, and in like circumstances the gift or receipt of money or other consideration is deemed to have been corrupt unless the contrary is proved. Local and public authorities of all descriptions are included in the expression "public body." By the Honours (Prevention of Abuses) Act, 1925, it was made a misdemeanour, punishable on indictment or summarily, to give or accept or agree or attempt to give or accept any gift as an inducement for procuring or assisting to procure the grant of a dignity or title of honour. And on conviction the gift is forfeited to the Crown.

(W. DE B. H.)

**United States.**—Bribery or corruption in American law is the offering to or receiving by any person charged with a public duty any money, favour or other thing of value to perform or refrain from performing such public duty. It is a crime, originally a misdemeanour, now a felony in practically all jurisdictions.

In order to consummate the crime it is not necessary that the person to whom the bribe is tendered should actually accept it or that his official action should actually be influenced by it. It is not even necessary that the money be tendered or produced. It is enough if it is offered. But a gift, not intended to influence official action, is not a bribe. It is no defence that the official accepting the bribe or the person offering the bribe was entrapped by the other party in an endeavour to get evidence and that such other party had no intent to influence official action. It is no defence that the bribe offered was worthless or that action or conduct desired by the briber was in itself proper. An officer is guilty who accepts a bribe to do his duty.

The official action sought to be influenced may be that of a judicial officer, or of other regularly appointed or elected officials, or it may be of juror, referee or appraiser, whose official duties and sphere of action are confined to a specific case. (The latter is called *embracery*, *q.v.*) Or the official action sought to be influenced may be the exercise of the elective franchise (*see* CORRUPT PRACTICES). Offences against the elective franchise are now generally covered in separate statutes and generally contain among their penalties on the one side the loss of the office voted for and on the other the loss of the right to vote for some fixed period.

The bribery statutes have in many instances been extended to cover attempts to influence the action of labour representatives, as to cause or prevent the calling of a strike, although such labour representative is not in strictness a public official or performing a public duty.

(B. RE.)

**BRIBRI**, an Indian tribe dwelling in the mountains of southern Costa Rica. They speak a Chibchan dialect, and belong to a group of related tribes collectively known as Talamancan. Although greatly reduced in numbers and under missionary influence in past centuries, the Bribrí maintain primitive cultural features suggesting South American origins.

*See* Alanson Skinner, "Notes on the Bribrí," *Indian Notes and Monographs*, Museum of the American Indian, Heye Foundation, vol. vi., No. 3 (1920).

**BRICK.** Though a common structural material, brick is the most remarkable one in use in the building industry. It is remarkable historically, technically, and artistically, and, it might almost be added, socially. Its history goes back to the earliest times in the civilization of man, and it bears on its surface written records of early ages that are most valuable. Excavations at Ur of the Chaldees, the city of Abraham, have yielded brick tablets inscribed imperishably with information about the life of a people living 6,000 years ago. The Sumerian palace at Kish, in Mesopotamia, built 3,500 years B.C., is another example of the ancient use of brick. It was discovered in 1925-6, and was found to be built of

small sized unburned bricks, set with mud joints. The paving was executed in burned brick. A peculiarity of these bricks is that they are plano-convex or cushion shaped, the curved face being laid upwards.

By some it is averred that brick was manufactured 12,000 years ago, and undoubtedly the tower of Babel was constructed of brick, if Old Testament records are to be believed. The walls of Babylon were built of bricks, burned and unburned. The former were 13 in. square and 3 in. thick, and from the ruins of the great city, burned bricks were removed and used for building more modern cities. Egypt has yielded numerous examples of brick, manufactured in the earliest and subsequent dynasties, and usually the bricks were large and unbaked. The step pyramid of Sakkara is one of the most ancient tombs in that region, and one of the most recently explored. The exterior of it was faced with stone or marble, long since removed, so that the brick structure stands revealed, and has endured through the ages. In Egypt, bricks were frequently impressed with the cartouches of kings for whom they were made, and by these their age can be known. Compared with these earliest examples, the bricks made by the Romans at the beginning of the Christian era, and by the Chinese, to build their great wall, at about the same period, seem almost modern, and yet the art which was developed in those days to a high pitch of usefulness was lost in Europe when the Roman empire fell.

Beautiful examples of brick have been found in the 20th century in India. The Paharpur temple in eastern Bengal was built in the 8th and 9th century, of small bricks laid in mud mortar, and was decorated with rows of terra cotta plaques of considerable artistic merit. This interesting discovery shows that the art was not lost throughout the world while Europe passed through the dark ages.

The excellence of the Roman manufactures is to be seen in England and other countries in which the Romans made bricks. They even developed the art of coating them with beautiful coloured glazes, of which many examples exist. About the time they introduced the art into England, they seem to have lost it in their home country, and none were made in Europe between the end of the 4th and middle of the 13th centuries. In England the Romans made bricks towards the end of the 4th century, and the manufacture ceased when the Roman occupation ended, until the Flemish came over to East Anglia in the 14th century.

**Revival After the Dark Ages.**—In Europe, the art began to be revived from the 12th or 13th century onward in Holland, Flanders, Germany, Italy, and England. From those days till the 19th century much beautiful brick and terra cotta architecture was executed, and has come down to the present day in monuments testifying to the artistic ability of their creators. Brick was used in Tudor, Jacobean, and Queen Anne architecture with an effect suited to and typical of the countryside and the climate of England, that has influenced the domestic architecture of the 20th century.

**Introduction of Machinery.**—About the middle of the 19th century brick manufacturers began the development of mechanical production. This progress was inevitable; increased population, increased industries, increased charters of liberty, all helped to cause an enormous expansion of a trade which henceforth was to be the prime factor in the housing of the people. Progress in making bricks was greater in England than in any other country because forests became denuded and stone was scarce in great areas of the land where cities and towns grew.

Brick manufacture was commenced in America about the middle of the 17th century, but it was not until the latter half of the 19th that the industry began to develop in that continent, when English machine-makers went over to seek a market. In Holland, Belgium, and France no real technical progress was made in the manufacture of bricks, until after the World War, although clay-working in other artistic branches reached a high state of perfection in France before the end of the 19th century.

**The Nature of Brick.**—A brick is essentially a small unit, for use in the construction of walls, piers, buttresses, and arches. By the massing of bricks in quantity with mortar joints of lime or cement, greatly varied forms of construction are erected, having massive or delicate proportions, but always capable of taking their

place as the supporting framework, for the carrying of floors, roofs, bridges, viaducts, and commercial structures involving the erection of machinery. Tall chimneys, too, are built with these small units of baked clay, and withstand the strain of storms and the ravages of climate. Brick is made of clay, a product of the breaking down by weather and other destructive agencies of ancient rocks of all kinds. Granite becomes clay, and man in the 20th century moulds this clay and bakes it until it becomes in some instances almost as hard as the granite from which it originated. Some clays again are made into bricks of far less strength than the parent rock, but yet are capable of withstanding destructive agencies such as water, frost, and fire. These agencies have destroyed the rock but leave the brick unscathed.

**Resistance to Fire.**—Some of the oldest clays found in conjunction with coal in deposits of the carboniferous age, those found as dry shale owing to the enormous pressure to which they have been subjected through countless centuries, form, when made into bricks, a material capable of resisting intense heat. The rocks, from which such shale was originally derived, would have perished and broken up, if subjected to such temperatures as are found in furnaces of many kinds used in industry. The rock could not be heated once in such furnaces without disintegration, but the fire-brick may be heated and cooled again and again, and still retain its form and properties. Stone used in building perishes gradually in the acid atmosphere of cities, but well burned brick, made even by the primitive methods of the early manufacturers, remains unharmed, and even improves in hardness by exposure. Brick, then, is a material of unchallenged durability and of unsurpassed usefulness in buildings and in industry.

**Seasonal Brickmaking.**—In the early times spoken of above, when brickmaking entered upon the period of progress, culminating in the highly technical processes of the present time, the manufacture was primitive and tedious.

Andrea Palladio, writing on architecture in 1570, says that drying bricks under shelter "can't be accomplished in less than two years." Up to the time when machinery was introduced, it was always necessary to dig the clay in early autumn, so that weathering under winter conditions rendered it fit for forming, by hand moulding, into brick shape. In smaller works this seasonal treatment still obtains in some parts of England, where surface clays of recent geological age are dug. Hand moulding of bricks, too, still persists in spite of the advent of the machine.

In the early days, the clay, weathered in heaps through the autumn and winter, was dug down from the heaps spread on the ground, watered and then "tempered" by being trodden by men's feet, till a suitable consistency was reached. This method of preparing the clay for moulding has been superseded for a century by the pugmill, a machine first driven by a horse and later by a steam engine, and in this the ground and tempered clay is ready for the moulder in far less time than by the old method. The pugmill of this class consists of a large wooden tub, without heads, set upright on the ground, and furnished with an iron spindle at the axis, carrying knives, which cut and compress the clay as it falls by gravity towards ground level. A rectangular hole, cut in the tub at ground level, allows the ground clay to extrude, so that it can be cut away with a spade and conveyed to the moulder.

**The First Brick Machine.**—One cannot discover who was the genius that realized the mechanical potentialities of this early clay-preparing machine. He saw that the extruded clay resembled in section the hole in the tub. He saw that a spade cut away a lump of ground clay of quasi symmetrical form, which might be considered to resemble a large brick. He, therefore, conceived the idea of placing the barrel on an iron platform, fitting the knife-carrying spindle with gearing, and applying steam power to drive it. He reduced the orifice in the tub to the size of a brick, and arranged rollers under the mouth, on which the clay could run without deformation of its rectangular shape. He used then a wire to cut off pieces of the clay column of the requisite thickness, and so a wirecut brick was made by a machine. Engineers soon perfected the machine thus conceived, and so the vertical pugmill brickmaking machine was produced from the old horse-driven mill of earlier days. Other brains came into play and decided

that the tub might lie on its side and the clay issue from the end of it, through a mouthpiece of suitable shape to make the clay column. This constituted the horizontal pugmill brickmaking machine, resembling a sausage machine in design and action. Instead of one wire to cut off one brick at a time, a "cutting table" was designed by which 10 bricks at once could be cut off by 10 wires carried by a frame. In due time the cutting table was also fitted with a power drive.

**The Use of Hard Marls and Shales.**—In the early part of the growth of the industry surface clays only were used for brick-

BY COURTESY OF THE BRIGHTSIDE FOUNDRY & ENGINEERING CO.

**HORIZONTAL PUGMILL, SHOWING THE OLDER MACHINES USED IN ENGLAND FOR WIRECUT BRICK MANUFACTURE**

It comprises two pairs of grinding rollers, mounted over a horizontal "auger" machine, provided with pugging knives and an expelling worm. At the end of the barrel a water lubricator "die" forms a rectangular clay column, which is cut off in long lengths, and slid forward on to the "slide delivery" cutting-table, which cuts it up into (usually) ten bricks

making, but when the horizontal pugmill was evolved other types of clay of earlier geological age could be worked. In order to break down these drier and harder clays, and bring them to the necessary plastic condition, heavy cast-iron rollers were introduced and mounted above the hopper of the pugmill. These rollers took various forms to suit different types of clay. After grinding through the rollers it was found expedient to chop the clay in the presence of water. To do this, horizontal trough mixers were designed with one or two long shafts fixed lengthwise, and carrying small knives along the whole length. A typical train of machinery for making wirecut bricks, then, came to be composed of two pairs of rollers for a preliminary breaking up of hard clays, then a double shaft mixer in which water is added to the clay, then two more pairs of rollers for finer grinding, and finally the horizontal pugmill with rectangular brick sized mouthpiece or die. Accessory to this train is the cutting table for cutting off the bricks to the required thickness.

For this plastic wirecut process, in which the clay must contain upwards of 25% of uncombined but thoroughly incorporated water, one other type of grinding machine has been largely adopted in the 20th century. It is called the wet pan and consists of a large flat-bottomed cast-iron dish, some 7ft. to 9ft. in diameter, with sections of the bottom perforated with holes or slots. A heavy vertical shaft in the centre carries heavy cast-iron rollers on the two ends of a horizontal cross shaft. These two heavy rollers, sometimes called edge-runners, are carried rapidly round and round the pan, and crush the clay thrown into it, forcing it gradually through the perforations in the pan bottom.

**The Need for Careful Clay Preparation.**—By whatever mechanical means it is done, the essential of modern practice is the complete and thorough preparation of clay before it is formed into brick shape. An approved practice is to interrupt the series of operations above described, just before the clay enters the pugmill, for the purpose of resting it for one or two days. The chemical or physical effect of this resting is not understood. But the "resting period" of mechanically treated clay is in some cases essential, and in all desirable, if the best results are to be obtained.

**The Semi-Dry Method of Manufacture.**—Towards the end of the 19th century a new method of making a brick from hard, almost dry, marls was devised. It consisted in grinding the clay, without added water, in a dry pan of construction similar to the wet pan above described. It differs only in that the pan revolves, and the horizontal shaft carrying the two heavy grinding rollers is stationary. An inner width of the pan bottom, on which the rollers revolve, is not perforated, but the outer half, annular in shape, is provided with fine holes. The dry clay is ground on the solid part of the pan bottom, and pushed by scrapers on to the perforated part. The finely ground particles fall through the holes, and the larger are pushed back under the rollers for further grinding. The powdered clay is again screened and the finest portion passed to the hopper of a powerful press. From the hopper an automatically measured portion is fed into a strong iron or steel mould with moveable plungers top and bottom. The top plunger descends, actuated either by cam, lever or toggle motion or in some cases by hydraulic power, and presses the clay particles together till they coalesce into brick form and size. The bottom plunger then pushes the pressed brick upwards out of the mould, and the "green" brick is ready to be burned in the kiln.

The brickmakers of Nottingham were persuaded that the bricks made by this process, from their hard marl, would supersede the plastic wirecut brick, and large quantities of semi-dry made bricks were produced and used in the town. But disaster overtook these manufacturers, for the bricks crumbled. Great pressure, then not attainable, is necessary to make a good brick by this semi-dry treatment. It is now known that for this type of clay from 75 to 125 tons pressure is needed on the brick. Although unsuccessful at Nottingham, the semi-dry method was adopted at Accrington in Lancashire with highly satisfactory results and practised for many years. Even here a third method called stiff plastic has been found more satisfactory.

**The Fletton Brick.**—The semi-dry method, however, found a home towards the end of the 19th century in a district where the Oxford claybeds are found in purest quality. In the Peterborough area of Northamptonshire some 10ft. of surface clay had long been worked by plastic process, turning out a brick of relatively poor quality. Beneath this surface, however, exists the Oxford clay, called in the district "Peterborough knotts" to depths varying from 30ft. to 60ft. or more. This material is a dry shale, not of such great geological age as the shale of the carboniferous period, but of similar appearance. It is characterized by the presence in it of a small proportion of mineral oil, and from 5% to 8% of carbon. This shale was found to respond readily to the semi-dry process of brick manufacture, and the bricks produced by it were square and hard, light in weight and colour, but cheap to make, because, firstly, they required no drying, and secondly, the carbon present in the clay proved to be almost sufficient fuel to burn them. A large industry gradually arose there. In 1927 the quantity of fletton bricks produced from the Oxford clay was well over 1,000 millions, or sufficient to build 50,000 modern workmen's houses. Works arose in Bedfordshire, Buckinghamshire and Lincolnshire, in which the same clay was found, all of which adopted the same method of manufacture. The fletton brick is the staple building brick of London, and is produced at such low cost that it can compete with plastic made bricks far from the Peterborough centre.

**Road Paving Bricks.**—Since the World War the semi-dry process of brick-making has found application to other clays both in England and on the Continent. By its means the hardest and strongest brick ever produced is now made, designed primarily for the paving of roads. For this brick a plastic clay is used, being first dried in order that it may be in a condition suitable for the grinding and pressing process above described.

**Stiff Plastic System.**—The stiff plastic process of brickmaking is intermediate in character between the plastic wirecut and the semi-dry. It is much used for working marls and shales in the north of England, and many plants are to be found in Lancashire, Yorkshire, Northumberland and elsewhere making building bricks, smooth faced facing bricks, firebricks and hard engineering bricks. In this process the marl or shale is ground in a dry pan and then

moistened in a horizontal mixer till it contains upwards of 12% of uncombined water, as compared with 20% to 25% in plastic bricks and 6% to 8% in semi-dry bricks. The press is similar in type to that used for semi-dry making, but, instead of dust, damp grains of clay are fed to a very short vertical pugmill, which forces the completed material into a mould in order to form an immature clot. On emerging from this mould, the clot drops into a finishing mould in which it is pressed into final form, ready for setting in the kiln. Large numbers of firebricks are now made by this method, although the old process of hand moulding is still considered to hold the field for the highest class firebricks.

**Hand-Moulded Facing Brick.**—The account given above of the development of mechanical manufacture, applied to the production of bricks of various classes, has perforce left out the original hand-moulding method of brickmaking, and has not dealt with the machinery used so largely in America, and to some extent in England, to imitate hand-moulding of the sand-faced variety. As stated above, hand-moulding is still favoured by the best class manufacturers of firebricks, and the production of this variety is of immense importance to the manufacturing trades of all countries in which high temperature furnaces are employed. The hand-moulding process of plastic manufacture produces the sand-faced red-facing brick, with all its modern variety of colour, a brick which for artistic effect in domestic architecture is as yet unsurpassed. The richness of texture and the gradations of colour cannot be equalled by mechanical means, and it is, and always has been, the characteristic facing brick of Great Britain, produced in no other part of the world. The surface clays and Bagshot and Reading beds which serve for the best of this type are found chiefly in the south-eastern fields. The clays are either weathered or mechanically prepared, and pugged in horizontal or vertical pugmills, already mentioned, ready for the hand-moulder. In its mouldable form the clay is very soft, so that when a lump of it is rolled in sand and thrown into a sanded mould, it readily flows into all parts of it, and when turned out on to a suitable pallet, is of good shape with richly sanded surfaces all round. It is then dried and burned in suitable kilns.

**The London Stock Brick.**—Another type of brick is made by hand-moulding called the stock brick or alternatively the London stock. The chief centres of its manufacture are Sittingbourne in Kent, Shoeburyness in Essex and Slough in Buckinghamshire, but many small yards are dotted about the south-eastern area which use the same process. In most, but not all, of these, the clay is mixed with washed chalk, which has the effect of changing the red colour obtained in burning to a yellow or brindle tone. In a few smaller yards chalk is not added, and the brick is dark brown in general tone. These bricks are moulded by hand, with sand used in the same way as for red-facing bricks. Very large quantities have been produced and delivered to London. The bricks are somewhat rough in texture, light in weight with porous body, this last due to the admixture with the clay of the fuel by which they are burned. Mechanical moulding of both sand-faced red-facing and stock bricks is now adopted by some manufacturers in England. The method is not so much an economizer of labour as it is a substitute for skilled men, who are scarce and difficult to train. In America enormous quantities of sand-faced common bricks are made mechanically, the type of machine being denominated the soft mud moulder. This machine is in the form of a pugmill of varied design, which presses the soft clay into a series of sanded moulds, three, five, six, or even nine side by side in one frame. The mould is filled with clay under the machine and then pushed out to a man in attendance, who strikes off superfluous clay, knocks the two ends of the mould frame to loosen the bricks, and passes the frame to a second hand. The mould frame is now placed face downwards on a long pallet and the bricks allowed to fall out of the moulds ready for removal for drying.

In France and Belgium one other system of moulding a brick has existed for many years and is still practised. It has not found favour in other countries. In the summer season only the surface clay found in great abundance in the north of France and in Belgium is dug, and without any further preparation fed to hand or mechanically operated presses, which press the damp

clay into brick form. In some ways this method bears a resemblance to the stiff plastic, but it is very primitive in character.

**The Drying of Bricks.**—The drying of bricks before burning is, in modern days, a process of great technical difficulty. The old way, still existing in many seasonal works, apart from the earliest method of laying the bricks out in single layer on the ground, was by means of sun and air, no artificial heat being employed. Large space is required for this method, an acre to a million annual production, and it has been almost entirely superseded by artificial dryers, except in small works and the large stock brick fields. The newly moulded bricks are set on edge in long single rows, and when one row is completed a second row is placed on it, and so on till the hack is eight or ten bricks high. The hacks, each with two rows of bricks, are arranged on flat open ground with space for barrows between and the bricks are protected from rain and wind by pent shaped covers and side boards. The bricks require from three to six weeks to become dry according to weather. The labour cost, loss by storms, and damage by handling render this system more costly than it would seem.

In large works in the Midlands and North of England recourse was early had to spacious shedding with floors, on which the bricks are laid, heated by exhaust steam from the power plant, and live steam from the boilers at night. This was found less costly than outdoor drying, and could be and is practised throughout the year in the majority of works making wirecut bricks.

**Tunnel Dryers.**—At the end of the 19th century, tunnel dryers were proposed and put on the market in Europe and America. In these a series of rail tracks of small gauge are laid in chambers upwards of 10ft. long and 6ft. high. Cars carrying wet bricks are closely loaded with spacing sufficient to allow the passage of hot air. The cars are pushed at regular intervals from one end to the other, while hot air is blown into the chambers in the reverse direction, drying the bricks on the cars progressively in their passage. At first this invention appeared to be technically correct in principle and economical in working. Experience, however, showed that, except for some types of clay which will withstand rapid drying without cracking or warping, this type of plant was much more costly than steam floors. The tunnel dryer is only economical if the bricks can be dried in 24 to 48 hours. Comparatively few clays will admit of such rapid treatment, and if longer time is occupied the capital charges and working costs become too great in proportion to output.

**The Humidity Dryer.**—The most recent advance in the difficult technical problem of rapid drying of bricks in the mass, is the adoption of a new principle termed humidity drying. It has been found that if a brick is heated in the wet state in an atmosphere saturated with moisture, until it attains a temperature of 120° to 150° it loses no moisture. It may then, however, be subjected to dry currents of air at the relatively high temperature of about 200° and will dry rapidly and completely in a very short time, without cracking or warping. Modern chamber dryers adopting this principle, combined with efficient apparatus for handling the bricks, are highly satisfactory for drying on a large scale and are far less costly than tunnel dryers.

**The Burning of Bricks.**—For the burning of bricks, in the early days of civilization, in Roman times, and in the period of revival in the 13th to the 18th century, small brick-built kilns or ovens were used, and the heat necessary was produced by wood burning in furnaces situated below the bricks set over them in open formation. Kilns of this type are still used with coal firing in many small works, and are generally known by the name of Scotch kilns. Much waste by over and under burning results in them, and the fuel consumption is as high as 20% of the weight of the burned goods. The down draught kiln, highly perfected in design, is a modification of this intermittent type of brick kiln. In this type an arched-over chamber is provided with furnaces in the external walls. The heat from them passes into the chamber over bag walls in the interior, and then downwards through the goods, descending finally into underground flues leading to a small chimney. Large numbers of this type of kiln are used in this country, not only for brick burning, but also for tiles, pipes, paving quarries, and other varieties.

In America, until recent years, this type was used almost exclusively for very large outputs. In this kiln the fuel consumption is still high, but the quality of the goods produced is as perfect as can be desired. Two important types of high-class bricks are burned almost exclusively in them, the blue Staffordshire engineering bricks, known all over the world as the iron brick, and glazed bricks of various qualities. While common and facing bricks are usually burned at temperatures from 900° to 1,000° C the blue bricks and glazed bricks require a temperature as high as 1,250° C.

Common salt is made use of in burning certain kinds of bricks in down draught kilns. The silver grey sand-faced facing brick made at Reading is one variety, which is very highly valued by architects for its artistic appearance. Salt is also used in kilns burning blue Staffordshire bricks, in order to create a reducing atmosphere in the later stages of the burning, and to form a thin glaze over the surface of the bricks. Salt glazed bricks made with a fireclay or stoneware clay are glazed by means of salt in a similar manner, and are much used for the plinths of large buildings in towns and cities and internally for lavatories, etc.

**Clamp Burning.**—A method of burning bricks in what are called clamps in England and county kilns on the Continent, was devised perhaps towards the beginning of the 19th century. No records appear to be available as to its origin. Prior to the World War it was the chief method in use in Belgium and the north of France, but has now been largely superseded by modern kilns. In England the method is still in use to a considerable extent in the stock brickfields described above, and in small works chiefly in the south. Clamps are large heaps of bricks stacked systematically as closely as possible. In England they are built of various sizes holding from 100,000 to 1,000,000 bricks, and generally about 10ft. or 12ft. high. On the Continent they are built much larger and higher, containing upwards of 3,000,000 bricks. The fuel for burning is usually incorporated in the mixture of clay and chalk, with a certain variable amount sprinkled between the layers of bricks. Fires are started in small channels at the bottom, and serve to ignite the fuel in and between the bricks. When once the fire has taken a good hold of the bottom courses no more stoking is needed, and the heat spreads gradually throughout the mass. In England it takes six weeks to burn a large clamp of

FROM C. F. MITCHELL, "BUILDING CONSTRUCTION," BY PERMISSION OF B. T. BATSFORD  
A PLAN AND CROSS-SECTION OF A HOFFMANN KILN

bricks throughout. In the continental system the firing is more rapid, and two or three weeks suffice for burning the large clamps where erected. The fuel is economically applied in this method but the results are uncertain and dependent on weather conditions. Waste by over and under burning is always considerable.

**Continuous Kilns.**—At the present time the majority of building bricks are burned in continuous kilns of two kinds. In the Hoffmann kiln, named after its inventor, the bricks to be burned are put in chambers in a massive brick construction. The chambers are contiguous, to the number of 16 to 24 in a kiln. They are disposed in two rows with semi-circular or rectangular ends, forming a complete circuit. The bricks are withdrawn after

firing and replaced by unburned goods day by day, and day by day also the fire, which is maintained for the burning of them, travels along from chamber to chamber. The actual firing takes place at a position about four or five chambers distant from the point where unburned bricks are being set and about seven to ten chambers from the point where burned bricks are being withdrawn. Adjacent to the point where bricks are being set, a damper is opened, giving passage for the gases of combustion towards a high chimney, which creates the draught required for combustion. A wall or damper of brown paper, pasted on to the green bricks, prevents external air from having access to the bricks in the last chamber set, so that the air and gases passing to the open damper must perforce be drawn through all the bricks set in the 14 to 20 chambers. The cycle of the burning operation therefore is, that cold air enters the back chamber where burned bricks are being drawn, and passes through a series of, say, seven to ten chambers which have been burned and are cooling. It becomes heated in doing so, recuperating and carrying forward the heat so acquired. It reaches then the zone of, say, two chambers which are being fed with coal, and serves to promote combustion. It then continues through the four or five chambers of green bricks set ready for burning, giving up a large proportion of its heat to them and heating them preparatory to being finally burned in their turn. The pull of the chimney draws the heat forward, causing the fire to travel through the chambers successively and continuously, so that each chamber in turn becomes heated, burned, and cooled ready for withdrawal and sale. This type was invented in Germany in the middle of the 19th century, and revolutionized the burning of bricks on a large scale. It quickly found users in England. It is exceedingly efficient in the use of heat, not requiring more than 6cwt. of fuel for 100cwt. of burned goods, instead of 20% used in intermittent kilns.

**The Tunnel Kiln.**—The second type of continuous kiln is known as the tunnel kiln, and differs from the first in the facts that the goods travel through the tunnel continuously, and the fire zone remains always at the same position. In other respects the principle is the same as in the Hoffmann type. Substitute the word cars for chambers and the description of the burning cycle is identical. The tunnel kiln is built upwards of 300ft. long, is rectangular in cross section, and at ground level is provided with rails, on which run cars carrying the bricks to be burned. Although actually conceived before the Hoffmann kiln, it is only in the years subsequent to the World War that the tunnel kiln has become a commercial proposition. Though simple in principle, great difficulty was originally encountered in obtaining uniform burning. An average dimension of the cross section of the tunnel kiln is about 6ft. square. The cars, about 6½ft. long and carrying, say, 1,200 bricks each, are pushed through the tunnel by hydraulic or gear-driven rams, a car being introduced every one to two hours and taking from 36 to 72 hours to pass from end to end. Tunnel kilns are fired either by direct burning of coal or mineral oil, or by producer gas generated in efficient gas producers. The amount of fuel consumed is similar to that of the Hoffmann type.

**Sand-lime Bricks.**—One other method of producing bricks may be briefly mentioned. The sand-lime brick, made largely in Germany, in America, and to a smaller extent in England and France, uses sand and lime as its raw materials instead of clay. About 10% of lime in a hydrated condition is mixed with the sand, and bricks are made by the semi-dry method in powerful presses. The bricks are stacked on cars and introduced into large boilers or autoclaves, which when full are closed. Live steam under pressure is then introduced into the autoclaves for a period of about 24 hours, hardening the bricks and rendering them fit for use in buildings.

**Value and Production in Great Britain.**—The foregoing relatively brief account of brickmaking cannot adequately convey to the reader the vast amount of technical detail involved in the successful carrying on of manufacture. Clays differ widely in characteristics and behaviour, no two kinds being treated in exactly the same way, or yielding exactly the same products. As the years pass, radical changes are made in the incidence of la-

bour. From being a trade of somewhat degraded character, brick-making has become highly specialized, producing goods of great variety with wide differences in value. A common building brick, for instance, such as the fletton, may be sold at works for 35s. per 1,000, a facing brick at 100s., an engineering brick at 150s., and a glazed brick at 300s. or more. The total production in England is over 5,000 millions annually. The cost of installation of modern works is in the neighbourhood of £3,000 to £4,000 per million annual production, so that the capital value of the industry, as apart from goodwill, is upwards of £20,000,000, and the turnover annually reaches approximately the same figure.

**The Strength of Bricks.**—The strength of bricks and brickwork is considered to be of considerable importance, in view of the function of brickwork as the framework of buildings and the support of the superimposed loads. The following table gives the ascertained resistance to thrust or, as it is usually termed, the crushing strength of standard qualities of bricks:

|  | Tons per sq.ft. |
|--|-----------------|
| London stock . . . . .                     | 100-150         |
| Sand-lime brick . . . . .                  | 160             |
| Hand-made red facing . . . . .             | 225             |
| Fletton . . . . .                          | 250             |
| Red marl brick Leicestershire etc. . . . . | 350             |
| Red marl brick North Wales . . . . .       | 500             |
| Red marl brick Lancashire . . . . .        | 950             |
| Staffordshire blue . . . . .               | 500-700         |
| Red or brindle engineering . . . . .       | 600-1,000       |
| Vitrified paving brick . . . . .           | 1,750           |

The strength of brickwork has been found, by the building research board, to be largely dependent on the strength of the joints made in building, and does not approximate to the crushing strength of the bricks used. A Leicestershire brick, for example, requires 350 tons per sq.ft. to crush it, but brickwork built with it in lime mortar fails at 100 tons, and in cement at 150 tons. A Staffordshire blue, built with cement joints, fails at 200 tons per sq. ft.

See A. E. Brown, *Brick Drying; Hand Brick Making* (1902); and A. B. Searle, *Modern Brick Making* (1920). (A. E. B.)

## AMERICAN BRICK

**Classes and Standards.**—In American practice a brick is a structural unit of burned clayey material, in the form of a rectangular block, with the standard dimensions of 2½in. by 3½in. by 8in. Bricks of other sizes, of other materials, and other structure than solid except limited perforations, have qualifying names, as:—fire bricks; paving bricks; sand lime, chrome, magnesite and silica bricks; insulating bricks; hollow bricks; Roman bricks, 1½in. by 4in. by 12in.; Norman brick, 2½in. by 4in. by 12in.; Old Virginia bricks, 3in. by 4in. by 9in., etc. The standard size of a fire brick is 2½in. by 4½in. by 9in. and there are standard sizes in key, arch, wedge, split and soap fire bricks.

The following standard sizes for paving bricks were adopted in 1927 by the National Paving Brick Association:

2½in. by 4in. by 8½in., plain wire cut bricks, laid the 2½in. depth.  
 3in. by 4in. by 8½in., plain wire cut bricks, laid the 3in. depth.  
 3½in. by 4in. by 8½in., plain wire cut bricks, laid the 3½in. depth.  
 3½in. by 4in. by 8½in., repressed block, laid the 4in. depth.  
 3in. by 3½in. by 8½in., Dunn wire cut lug block, laid the 3in. depth.

**Bond in Bricks.**—Bricks are bonded into durable products in the process of burning by the fusion and subsequent hardening of the alkaline minerals and mineral salts, denominated fluxes, present in the clay. As fusion and solution of the refractory grains progress with advancing temperature the ware changes from soft, to light hard, to hard, and finally to a vitrified product. In the latter the fused matrix predominates. The porosities range from as high as 25% in the soft bricks to 10% or less in the hard bricks and to 5% or less in the vitrified bricks.

**Processes.**—The processes used in America are the *soft mud*, the *stiff mud*, and the *dry press*. The *stiff plastic* process intermediate between the stiff mud and the dry press, used in England is not used in America except to a limited degree and in a modified way in the manufacture of some fire clay products.

The soft mud hand moulding operation has been discontinued in America except in the manufacture of fire bricks and in this product it is gradually being superseded by other processes.

**Soft Mud Machines.**—Soft mud machine moulded bricks were first made in America in 1833, and next from 1840 to 1844 in Philadelphia, Pa. Within a few years machine moulding became the general practice but it did not entirely displace the hand moulding for nearly 40 years.

The maximum output of these machines was about 30,000 bricks per day which was the labour limit in striking to remove surplus clay from the moulds and bumping the moulds to loosen the bricks for dumping. The modern moulding machine is automatic. The mould sanding and feeding, the striking and the bumping, are done mechanically, and the labour required is performed by one man who places the pallets on the dumping frame. In the majority of installations wire rope carriers take the loaded pallets to the drying racks. With hand labour practically eliminated the soft mud machines produce upwards of 100,000 bricks per day.

In the most modern plants the dry bricks are taken from the pallets in units of ten or less as may happen, and set on cars in units of 500 to 1,000 bricks as they will be set in the kilns. A crane equipped with a lifting fork sets these larger units in the proper place in the kiln in a single operation.

**Dry Press Machines.**—The first dry press of which there is record was put into operation in 1847 and in 1848 many such presses were in use. In 1856 a hydraulic press was built in Cleveland, Ohio, and was subsequently developed and put into operation in St. Louis, Mo.

These presses, which made ten bricks with each revolution of the machine became the basis of a large production which still continues. In 1878 a toggle joint press of American design was put into operation in Chicago, Ill.

About 1880 a number of toggle joint presses were developed and became the basis for a large output of dry pressed bricks throughout the country, though the peak of such production has long since been passed.

**Stiff Mud Machines.**—In 1853, James W. Penfield of Wiloughby, Ohio, designed and put into operation a horse driven, intermittent, horizontal plunger, stiff mud machine which became the basis of an extensive manufacture of plunger stiff mud machines and a large output of stiff mud bricks. In 1862, Cyrus Chambers of Philadelphia, Pa., built and put into operation a stiff mud auger machine so-called the "sausage machine" with an automatic cutter, driven by steam power. This was the beginning of the numerous output of stiff mud bricks which predominate the market. In 1928 there were many factories which produced more than 100,000 bricks per day from a single machine, and in the Chicago district, where a crane with lifting fork to set the bricks in the kilns in large units is used, the output from a single machine is about 300,000 bricks per day.

**Grinding Machines.**—The clay preparing machinery is adapted to the nature of the clay or shale utilized. Granulators, disintegrators and rolls are used for soft clays, and dry pans for hard clays and shales. In the United States the dry pan with a capacity from 75 tons to 150 tons per day, depending upon the hardness of the material and the fineness of the grinding, is being replaced by a machine designated as a grinder which, in the heavier types, has the capacity of four or five dry pans, or a ton of ground clay per minute. The grinder differs from the dry pan in that the screening feature of the latter is entirely or largely eliminated in the former, and the rollers have been increased in weight in the heavier machines to upwards of seven tons each.

**Equipment.**—Where sorting is not required, clays are gathered by various types of scrapers but the machine chiefly used is a steam or electric driven shovel, commonly known as a steam shovel. When the material will stand in a vertical bank, a shale plunger is used. This is a powerful chain elevator of the bucket type, but instead of buckets, cutting chisels are attached to the chains. This equipment cuts the material from top to bottom in a shallow cut, the cuttings dropping through chutes into industrial railway cars. As the cutting proceeds the machine advances automatically along the vertical bank. The dug material is hauled to

the factory by small locomotives (*dinkeys*). In the factory the lump hard clay or shale is dumped into a reciprocating feeder which spills it into a jaw, gyratory, or single roll crusher, the latter being the most widely used. The crushed clay is then conveyed to the dry pan or grinder into which it is automatically fed by a reciprocating or disk feeder. The pulverized clay is elevated, screened, and conveyed to the brick machine—stiff mud for example—and fed into the pugmill by a disk feeder. Excess clay from the grinders is dumped into a storage bin to be used as occasion requires. Much heavy labour is thus eliminated.

**Dryers.**—Open yard drying has largely disappeared and air drying in racks is disappearing. In their place several types of artificial dryers are used, the type depending upon the available heat supply. The most widely used dryer is the tunnel type, in which the bricks on cars in units of 500 to 700 are moved through tunnels on tracks. The combustion gas type, designated as a radiated heat dryer, has ducts for the smoke gases under the tunnel tracks; the common form has furnaces at one end of the dryer, connecting with the combustion gas ducts. In some installations the combustion gases from burning kilns are collected by fans and forced through the ducts. The progressive tunnel dryer collects the hot air from the cooling kiln, from steam coils heated by exhaust or live steam, from auxiliary furnaces, etc., and thus the heated air is put directly into the drying tunnel and comes in contact with the ware. Most tunnel dryers are distinctively humidity dryers since the ware is moving in one direction and the hot air, with its accumulated vapour and decreasing temperature, is moving in the opposite direction. In the newer forms of humidity dryers the main features are better air circulation among the ware and better control of the humidity. For soft mud bricks the pipe rack dryer is widely used. This consists of racks of closely spaced steam pipes upon which pallets of bricks rest. Fire bricks, because of the need of repressing after partial drying, are largely dried on steam heated floors, known as hot floors, though tunnel dryers are used to an increasing extent where the newer processes of manufacture have been adopted.

**Kilns.**—Every type of kiln is used. The original common clamp kiln, known as the scove kiln is used in some of the largest common brick operations. This type of kiln lends itself admirably to operations where the bricks are set by machines. Many factories use the up-draft kiln which is identically a clamp kiln except the walls of the kiln are heavy and permanent. The down-draft kiln is most widely used, despite its greater fuel consumption because of the excellence of the results due to the effective control that it provides over the kiln atmospheres. This insures the production of every possible colour effect by oxidizing and reducing conditions, and also special colours by the use of minerals or salts in the final stages of the firing, such as zinc to produce a green color, manganese to produce black, common salt for glazing, etc. Among the economizer types of kilns are the tunnel kiln, the compartment continuous kiln and the car tunnel kiln. The tunnel kilns often exceed 24 sections in length and are operated with two or more sets of fires, or in other words are operated as two or more kilns. The largest kiln of this type in America in 1928 was in Bessemer Quarries, Ohio, producing paving bricks. This has 208 sections and when in full operation 10 sets of fires are carried at the same time. The kiln is built in two parallel batteries, connected at the ends, and, if straightened out into a single battery, it would be more than a half mile long.

The compartment continuous kiln is an advance over the tunnel type, in that the draft often is distinctively down draft instead of being horizontal draft or serpentine draft as in the tunnel kiln and other solid floor kilns. This is used in many localities but since the advent of the car tunnel kiln but few new compartment kilns are installed. The car tunnel kiln, built in lengths of 300 ft. to 400 ft. and producing from 40,000 to 70,000 standard bricks per kiln per day, was in 1928 rapidly coming into use for the production of bricks and fire bricks.

**Bloated Bricks.**—Clays containing carbon and sulphur minerals, notably iron pyrite, if burned too rapidly in the early stages of the firing during oxidation, bloat when the temperatures are carried up to the finishing point. This condition is commonly

termed *black coring* because the core of the ware is black from the unburned carbon and the reduction of the iron. The bloating is due to the entrapped gases which cannot escape as vitrification of the clay takes place. In many instances such bloated ware will float in water. During the World War bloated burned clays were produced for the building of concrete ships, and since are finding use in making light weight concrete and light weight building tile.

**Texture Bricks.**—From Colonial days to the advent of the dry pressed bricks, the bricks were rough, misshapen and irregular in size. The better grades were selected for line (face) bricks and the poorer grades for inwalls. With the appearance of the dry pressed brick, uniform in size and perfect in form, the distinction between common and face, or pressed, bricks became sharply drawn. The manufacturers of stiff mud bricks met the dry press standard by re-pressing the bricks in a press akin to a dry press. Then followed an era of construction with perfect bricks, uniform in colour and laid with thin mortar joints. The bricks comprised the sole structural feature of the wall. In 1903 in New Lexington, O., the wire-cut texture brick was first produced. Wires were stretched across the die to cut off a thin slice from the surfaces of the stiff mud bricks, leaving a rough serrated surface. The artistic value of this surface texture was quickly recognized by architects and the manufacture of wire-cut face bricks spread throughout the country. Numerous other textures have been produced by various scratching devices, to some of which distinctive names have been given, as *tapestry*, *rug*, *oak bark*, *raglan*, *velvet*, *astrakhan*, etc. With the advent of the texture brick the mortar joint, formerly merely a structural factor to be hidden, has come to be recognized as a characteristic feature in brick wall construction. Uniform shading has given way to mingled shades including every colour and shade possible in burned bricks. The American wall built of all stretchers with hidden bond, has given way to various bonds—English, Flemish, Dutch and a wide range of diaper work. The production of polychrome glazed colour effects, produced by spraying the stiff mud bricks with glazes, has begun to off-set the increasing use of terra cotta products.

**Scum and Efflorescence.**—A white coating on bricks from the kiln, known as *scum* or *whitewash*, and white, yellow to green coatings which come to the surfaces of brick walls, known as *efflorescence*, are serious brick making problems.

**Rattler Tests.**—Paving bricks are tested in a machine known as a *rattler*, adapted from a similar machine used in foundries for cleaning castings. It is approximately a cylinder, 28in. in diameter and 20in. wide. The periphery is made of six inch channel bars bolted to the side frames and slightly spaced to permit the escape of the dust. These are lined with steel staves. The charge consists of about 100 pounds of the bricks, 225lb. of one inch and 75lb. of four inch cast iron balls. In the test the machine is rotated at the rate of 30 revolutions per minute for a period of one hour. The loss in the weight of the bricks by abrasion is termed *rattler loss*, and specifications for paving bricks commonly range between 18% and 24% rattler loss.

**Output and Value.**—The U.S. Department of Commerce report for 1926 gives the following statistics regarding the industry:

|  | Number of establishments | Output in thousands | Value        |
|--|--------------------------|---------------------|--------------|
| Common bricks . . .  | 1,220                    | 7,520,411           | \$88,249,925 |
| Face bricks . . .  | 456                      | 2,439,820           | 44,516,336   |
| Vitrified bricks . . .   | 131                      | 467,580             | 10,284,741   |
| Hollow bricks . . .  | 39                       | 63,359              | 692,258      |
| (This does not include hollow building tile having a value of \$23,560,571.) |                          |                     |              |
| Enameled bricks . . .  | 9                        | 15,441              | \$1,275,692  |
| Fire bricks . . .  | 244                      | 1,016,879           | 40,992,018   |
| (This does not include 40 establishments making special refractory shapes.)  |                          |                     |              |

The total value of all clay products in the United States in 1926 was \$459,049,470.

Labor Stat., Bull. No. 356* (1924); and A. I. Andrews "The Making of Dolomite Brick," *Ohio State Univ. Engr. Serv., Bull. No. 31* (Columbus, O., 1925).

(E. Lo.)

**BRICKFIELDER**, a term originally used in New South Wales for a hot scorching dust-laden northerly wind of the sirocco class blowing from the interior, where the sandy wastes, bare of vegetation in summer, are intensely heated by the sun. The name has been extended to similar winds in other parts of Australia. These hot winds blowing strongly, often for several days at a time, defy all attempts to keep the dust down, and parch all vegetation; but being exceedingly dry and hot they also destroy injurious disease germs. The northern brickfielder is almost invariably followed by a strong "southerly buster," cloudy and cool from the ocean. The two winds are dependent on the same cause, viz., a cyclonic system over the Australian Bight. These systems frequently extend inland as a narrow V-shaped depression (the apex northward) bringing the winds from the north on their eastern sides and from the south on their western. Hence as the narrow system passes eastward the wind suddenly changes from north to south, and the thermometer has been known to fall 15 degrees in 20 minutes.

**BRICK OVEN.** In colonial days in the United States the brick oven, also known as the baker's oven, was used in the home as well as by bakers, to cook by conserved heat. It was built in beside the kitchen fireplace, usually with an arched top. The doors were first of wood, protected on the inside by a sheet of metal. Later iron doors with a draught were used. A hot fire, often of brushwood only, was built in the oven and the iron door closed with the draught open, or the wooden door left slightly open. When the fire had burnt out, the ashes were raked out, the food set in the oven and the door closed without draught. To place and remove the food there was used a slice or peel—a long-handled iron tool with a flat blade to slip under the pot or pan. Many of these ovens were very large, so that many loaves of bread, pies and cakes could be baked at once. The colonial housewife often baked 40 or 50 mince pies in one day, piled them one on the other in a storeroom where they would freeze, and re-heated them when required in the Dutch oven (*q.v.*). These ovens still exist in colonial houses and are sometimes used by lovers of old ways. They are an early form of fireless cooker (*q.v.*).

Brick ovens were also extensively used in England and still are in many country districts.

**BRICKWORK.** This term is not restricted to simple edifices of bricks, but includes vaulting, tracery, moulding, carving, and gauging for decorative as well as for purely structural purposes.

FROM "A HISTORY OF ENGLISH BRICKWORK"

FIG. 1.—PROFILES OF 16TH, 17TH, AND 18TH CENTURY BRICK CHIMNEY CAPS. THE SAILING COURSES DO NOT PROJECT MORE THAN 1½ INCHES AND THE BRICKS ARE ALL ABOUT 2¼ INCHES THICK

Brickwork may be either of sun-dried or of burnt brick. Both kinds were built at very early periods and are often found together, even in the same wall. Probably the choice between construction of walls of mud (as in Peru and Mexico) or of mud bricks (sun-dried, as in ancient Egypt) depended upon the nature of the clays available.

**Antiquity.**—The oldest brickwork known is the Sumerian, in the area between the rivers Tigris and Euphrates. Recent investigations at Ur have revealed brickwork earlier than the first dynasty—say before 3200 B.C., and many buildings have been uncovered of date 2100 B.C. Such brickwork has many of the

characteristics of modern structures. The bond (*see* p. 120) is carefully kept and stability is secured by headers being carried through into a rubble core behind the brick facing. For important buildings bitumen was used for mortar, for ordinary work the bricks were bedded in mud. Lime mortar does not appear to have been used until the 7th century B.C. Several corbelled arches and vaults were found of date 2100 B.C., and a doorway which had a vaulted arch. This was built of bricks about 10 x 7 x 8 inches. The bricks were not cut as *voussoirs* but had radial (wedge shaped) joints of mud.

The enormous area of ruined brickwork at Babylon is well-known. The Babylonian bricks measured 13x13x3-3½ in., with headers 13x6x3-3½ inches. The joints were about 1½ in. thick and were either of mud or of bitumen. Vast quantities of burnt brick were used. The towers of the Gate of Ishtar (40ft. high) built by King Nebuchadrezzar (605-562 B.C.) originally had 575 representations of animals in relief. (*See* Plate I, fig. 1.) These were the sacred Bull of Ramman, the weather god, and the dragon of Babylon, or Sirrish. Probably the bricks modelled with these bas-reliefs were made in pottery moulds and touched up with some polishing instrument before burning. The portion of the Gate of Ishtar illustrated, was carried out in burnt clay, which, like all the bricks there, is of the same yellowish brown colour as the sand around.

The Greeks used both sun-dried and burnt brickwork and it is recorded of King Agis II. of Sparta that, in 418, he dammed up the River Ophis below the town of Mantinea, through which it flowed, so that the waters sapped the walls of the town, which were built of sun-dried brick. Such brick was preferred by the ancients to burnt brick for defensive works because it was tougher, and for this reason when Mantinea was refortified sun-dried brick was again used but the river was diverted to prevent recurrence of the disaster. The use of these crude bricks for building seems gradually to have given way to brickwork in burnt brick, though instances occur in comparatively modern buildings, as in some old Norfolk cottages, where unburnt bricks are still to be found, usually in inner walls. Sun-dried bricks were used also by the Romans, and Vitruvius (engineer and architect, temp. Julius Caesar and Augustus) gives detailed instructions as to their manufacture. They were made in moulds, whilst the burnt bricks (actually large, thick tiles) were made of plastic clay, beaten flat and trimmed to rectangular shape. In England, as also elsewhere, the art seems to have died out with the fall of the Roman Empire, and until the mediaeval revival such brickwork as was built was of Roman material re-used.

**Mediaeval Brickwork.**—The mediaeval revival developed the use of brickwork from simple structural to highly decorative purposes. Brick units were cut first in simple forms as in the apse at Torcello, 12th century (*see* Plate I, fig. 2), the character of which is not Lombardic but Byzantine. The large zig-zag pattern of the cornice is found also in Constantinople, in Salonika and in Italy at Padua and Murano. The bricks measure 9½x4½x2½ in. but large flat bricks are cut to fill the spaces under the chevrons. From these simple forms later brick-builders cut and assembled ordinary bricks into an immense variety of decorative features which passed through specially moulded brick units to all the most elaborate designs in terra cotta. In Spain, the three great brickwork districts of Aragón, Andalusia, and Castile abound in interesting examples. At Ternel, in Aragón, the House of the Templars has a cut and moulded cornice of interesting section. Here the bricks are thin (about 1½ in.), of a deep crimson colour, which, set in joints as thick as the bricks themselves, present a rich, glowing effect. At Tarazona is a high tower, built in stages; the arcading, panels, strings, and strapwork of which are formed almost entirely of plain, unmoulded brick; the bricks, which are large and thin, are set with wide joints. The effect close up is coarse, but at a little distance most effective. Lubeck (Schleswig-Holstein), one of the principal Hanse cities, has five Gothic churches and many other important buildings built of brick, while the East end of the church at Prenzlau, Prussia, has rose window, arcading, and tracery all of the same material, forming a remarkable and beautiful achievement in brickwork. Many

mediaeval French castles were of brickwork. In these diapers and patterns were often formed, not only by the use of dark headers but with bricks of different colours as long before manipulated in Italy. Plate I, fig. 5 shows a 14th century dovecote at Boos near Rouen, where the brick panels are treated in a diversity of ways by arrangement of bricks in patterns and by the use of bricks of several colourings.

**Revival in England.**—War and commerce were the two chief factors in the introduction of brick into England in the mediaeval

FROM "A HISTORY OF ENGLISH BRICKWORK"

period. English knights who captured and occupied castles in France returned to England and built similar castles for themselves—frequently in brick. Tattershall Castle, Lincolnshire, c. 1431-49; Caister Castle, near Yarmouth, built after 1424, and Hurstmonceux Castle, Sussex, 1445-46, are notable instances. Whilst there can be no doubt that these popularized brickwork as a building material, its re-introduction into England was of earlier date and was actually due to commerce. The Hanseatic League, originally an association of merchants, became a federation of great cities of the Baltic and Low Countries; just that area where the scarcity of stone made brickwork universal for buildings. The origin of the Hanse is remote and unknown. Lubeck, the principal Hanse city, was founded 1143. There, at Quedlinburg, and elsewhere in Prussia brickwork of the 12th century is found. Norwich, Lynn, Boston and Hull were amongst the League towns in England, and, of these, Hull was the most important. Wherever the Continental agents of the League settled they seem to have introduced the art of brickmaking and building. Hull was a centre of these activities; by 1303, the corporation had its own brickyards, from which it supplied bricks. War between the League and England hindered development, but when in 1474, its privileges were restored there was a marked impetus given to building with brick in eastern and south-eastern counties,

## CHARACTERISTIC TYPES OF BRICKWORK FROM THE 5TH CENTURY B.C. TO THE 16TH CENTURY A.D.

1. Gate of Ishtar, Babylon
2. Detail of apse of St. Fosea's church, Torcello, Venetia
3. Inner gatehouse of Little Leez priory, Essex
4. Chimneys of Hampton Court palace, near London
5. Boos manor, near Rouen, France
6. Pebmarsh church, Essex

## ENGLISH BRICKWORK OF THE SIXTEENTH, SEVENTEENTH AND EIGHTEENTH CENTURIES

1. Gauged brickwork at Kew Palace, London, dated 1631. Ionic caps and window arch-key of carved brick
2. Mid-16th century octagonal chimneys of axed brick from a farmhouse in Crundale, Kent
3. Mid-17th century work, High street, Godalming, Surrey. Strapwork in panel, cornices in axed brick
4. West window of the Layer Marney Church, Essex, about 1520, showing brick mullions
5. Styles of brickwork, early 18th century, from Bradbourne house, Larkfield, Kent. Left, gauged brick plaster in two colours; right, contemporary walling, bricks fairly regular in size and form
6. Late 17th century finely gauged brickwork, from Enfield, Middlesex, now in Victoria and Albert Museum
7. Detail of Tudor brickwork from Little Leez priory, Essex, about 1538

in certain districts of which brickwork almost entirely superseded stone. It must be remembered that this brickwork was not confined to mere building of walls. The most remarkable East Anglican churches, castles and halls, in which the use of brick included every current elaboration, were erected between this date and the Reformation—a period of 50 or 60 years. Of these Oxburgh Hall, Norfolk, 1482; Gifford's Hall, Suffolk, early 16th century; St. Andrew's Church, Sandon, Essex, c. 1502; Layer Marney Hall and Church, Essex, c. 1520; Hampton Court Palace, c. 1520; Sutton Place, Guildford, Surrey, c. 1523, and Little Lee Priory, c. 1539 (Plate I., fig. 3) are conspicuous instances. The character and appearance of brickwork of this period (early 16th century) are clearly shown in Plate I., fig. 6 of the porch of Pebmarsh church.

Thus example and instruction provided by settlers from the Continent, together with the impulse of fashion set by great and powerful lords, were the primary causes of the re-introduction of brickbuilding in England. It is questionable, however, whether these alone would have been sufficient to establish the art had other necessary factors been wanting, for it is rather owing to its inherent qualities and to convenience that brickwork has so firmly established itself in public favour. Reference has been made to the fact that scarcity of stone in the Low Countries encouraged the use of brick there, and for the same reason it became almost exclusively used in some districts in England. Mention should also be made of the convenience of handling bricks, the dimensions of which, though varying slightly at different periods and in different parts of the country, were such that a bricklayer could pick up a brick with one hand and use the other to spread mortar. A further recommendation of brickwork was its durability. Sound, well-burnt brick, set in good lime mortar, will resist the weather for centuries, even in the English climate; indeed, the limit of its resistance has not yet been reached, for brickwork built over 600 years ago is still sound and likely to stand as much longer, providing no more destructive agency than Nature attacks it.

**Modern Brickwork.**—Although brickwork construction is often found cheaper than building in stone, the widespread belief that it is "common" or inferior to stone is incorrect. It is actually superior to stone in strength and in durability, whilst in form, colour and texture good brickwork is unrivalled. Just as the builders of castles in the 15th century chose brickwork and even introduced the art of brickmaking into the country to obtain it, so Cardinal Wolsey and Henry VIII. employed it in building Hampton Court Palace (upon which they spared no expense) and Sir Christopher Wren used it for his addition there, associated with stone; at Christ's Hospital by itself and at Morden College with painted plaster: all these with a view to securing results which could be obtained in no other way. The Georgian architects continued these themes, until, towards the end of the 18th century, stucco gained favour and brickwork, though still employed, disappeared from view. During the dreary mid-nineteenth century, which the French so happily term "*L'Époque du mauvais goût*," yellow brick was largely used to build unlovely square houses and more unlovely eccentric ones. This continued up to the third quarter of the 19th century, when a brick revival took place, following the publication of G. E. Street's "*Brick and Marble Architecture in Italy*," in 1855, the chief effect of which was an eruption of "Venetian" doorways and windows in gauged red brick. Contemporary with and following him, William Butterfield indulged in riots of coloured brick disposed in patterns and in "Gothic" devices, some of which (as the Rugby school buildings) earned the description of "streaky bacon" architecture. Alfred Waterhouse was also tempted by the facility of the material to indulge in remarkable feats of elaboration in brick and terra cotta, as at the Natural History Museum, South Kensington, completed 1880. Such extravagancies were followed by natural re-action, their ultimate effect was to discredit brick as a building material, and imitation of the Butterfield and Waterhouse eccentricities by every suburban villa-builder completed the degradation of brickwork. This was further precipitated by the association of brickwork with the Gothic revival, when architectural fashion turned to the Renaissance manner as the only one suited

for buildings adapted to modern requirements. Meantime two architects were producing works which had far-reaching effects upon design, and, incidentally, upon brickwork design. Norman Shaw was the pioneer of the revival of traditional architectural design; Philip Webb of the appreciation of use of materials. It was only necessary that the right ways should be indicated, for to no building material were such attitudes of mind more applicable than to brickwork. War, economy and consequent restrictions have necessitated pruning brickwork of all but essentials, and the tendency is now to depend upon colour and texture—combined with good proportion rather than upon elaboration of detail.

### BRICKLAYING

Certain essentials in building good brickwork are:—Accuracy in working to ensure a perfectly horizontal bed and that walls are vertical, or, if the outer face is battered (sloped), that the angle of the batter is maintained. A bricklayer usually first builds up the quoins (angles of building) six or eight courses high, and having got these absolutely true he proceeds to lay courses the whole length of wall between. For the quoins he uses his square, spirit level and plumb to ensure accuracy and then stretches a line the exact height of the next course he has to lay for the whole distance between the quoins. Bricks are laid with the frog (the hollow on one side of the brick) uppermost. It is essential that all joints should be filled with mortar ("well flush up the cross joints"), otherwise the work will be weak. This is so obvious as to appear unnecessary to mention, but bricklayers habitually neglect to flush up and that this must be done has to be impressed frequently upon the foreman. In dry weather bricks must be wetted. Men will not dip them into a bucket of water as they lay the bricks because this makes their hands sore. It is usual, therefore, to pour water over bricks before they are laid or to do so on each course, as laid. Neither method is entirely satisfactory but either is better than perfectly dry bricks, which absorb the moisture from the mortar before it has set, so that it never really unites with them. In wet weather bricks should be protected from excessive rainfall or this will protract the setting of mortar and work will not be ready for succeeding courses when it should be. Brickwork must not be carried up too quickly lest the work should settle and so be out of plumb, for this reason it is usual only to carry up work three or four feet at a time, and to do so evenly all round the building.

**Mortar.**—Good brickwork implies good mortar, whether of lime or cement. If the sand used is not clean and sharp, or if it is earthy the mortar will not be strong. Lime mortar should be used within ten days of mixing; cement mortar should be mixed in small quantities and used within half an hour. (*See MORTAR.*) The effect of frost upon mortar that has not had time to set hard is to destroy its properties. The exact degree of cold at which bricklaying should be stopped depends upon several factors, but the addition of a proportion of unslaked lime (the amount of which will vary with the degrees of frost registered) will enable work to be continued for some time. Green brickwork may be protected; but the perfunctory protection afforded by laying empty cement bags or a tarpaulin over newly built work is negligible.

**Bonding.**—Bonds are the arrangements of bricks by which each brick overlaps another by a quarter of its length or  $2\frac{1}{4}$  inches. Bonds are recognised by the arrangements they present on the faces of walls and frequently the substitution of one bond for another may enhance the appearance of brickwork without impairing its strength; although the primary object of bonding is to secure the greatest possible strength to the structure. Only four bonds are *commonly* found in England. They are English, Flemish, Stretching and Flemish Garden Wall bonds. The first three are used for buildings, the last one for single brick (9in.) walls where both sides of the wall are seen. There is no reason, save lack of enterprise, why other bonds should not be employed. In fig. 3 bonds are illustrated, the arrangement on face and return walls being shown in each, together with a short definition to assist in distinguishing one from another. English bond, which consists of alternate courses of headers and stretchers, is regarded as the

strongest of all. English Cross bond and Dutch bond are merely variations of it: used for an unbroken wall surface, they produce a multitude of little crosses, which form a pleasant variation but too much of which is distressing to the eye. Flemish bond consists of alternate headers and stretchers in the same course, and is inferior in every respect to English bond, though preferred by those who strive after "neatness." It was introduced into this

FROM "A HISTORY OF ENGLISH BRICKWORK"

Fig. 3.—English Bond has alternate courses of headers and stretchers. In English Cross Bond stretchers break joint. Flemish Bond has alternate stretchers and headers. In Heading Bond, all bricks are headers except at the quoin. In Stretching Bond, all bricks are stretchers, except the alternate headers of the quoin. In Flemish Garden Wall, three stretchers, then one header in every course; in English Garden Wall, three stretching courses to each heading course. Monk Bond has two stretchers, then one header

country about 1630; not by William III., as often stated, though by the end of the 17th century it had almost entirely supplanted English bond. Heading bond is obviously weak and is only used where strength is not required and for curved walls. Stretching and Facing bonds are used for walls of only half brick ( $4\frac{1}{2}$  in.) thickness. Both are ugly and it is surprising they should be tolerated.

Flemish Garden Wall or Sussex bond consists of three stretchers to one header, repeated in the same course and, as stated above, is used for 9 in. walls. The reason is that, owing to the unequal shrinkage of bricks in burning, lengths may vary as much as  $\frac{3}{4}$  in. and some headers in single brick walls built in English or Flemish bonds would project beyond others, producing an unequal and lumpy surface. By using Garden Wall bond fewer headers are needed, and these are picked out to one length before building is begun. English Garden Wall bond consists of three courses of stretchers to each course of headers. In the North of England five courses of stretchers go to one course of headers and this is also the practice in the United States, where this bond is called common bond. Like Flemish Garden Wall bond, bricks of even length are picked out for the header courses before the work begins. Either of these Garden Wall bonds may be used instead

of Stretching or Facing bonds for half-brick walls (e.g., the outside skin of a cavity wall). The additional cost, if any, is trifling, for the headers will be half bricks (snap headers) in such walls and there are always some broken bricks which can be used up. The improved appearance by comparison with Stretching Bond is remarkable.

Yorkshire or Flying Bond has no practical value. It was in vogue at a time before bonding was thoroughly understood in England. Monk Bond consists of two stretchers and then a header throughout in the same course. It is the bond used for centuries in Northern Germany and Scandinavia. Over a large wall surface it produces a series of chevrons five courses high—a pleasing variation which is not worrying to the eye. By modifying it, and using headers with burnt ends (grey ends), vertical bonds may be produced, but these will be referred to later.

**Types of Brickwork.**—English brickwork may be divided into three distinct types:—

1. The Tudor, Plate II., fig. 7, in which the bricks are rough in form, are twisted, are irregular in outline and are built with joints from  $\frac{1}{2}$  to  $\frac{3}{4}$  in. thick. These bricks vary much in colouring and include plum reds, yellow reds, browns and bluish greys. Few modern attempts to produce Tudor brickwork include all these characteristics, yet no brickwork is so generally admired as the old.
2. The 18th century brickwork, Plate II., fig. 5, a type which actually came into fashion in the latter part of the 17th century. The bricks are regular in size and form, with sharp arrises (edges); they are built with joints never exceeding  $\frac{1}{2}$  in. (often only  $\frac{1}{4}$  in.) thick, and the bond is usually Flemish. Bricks vary with the clays of the locality in which they are made, from deep red to the yellow and grey stocks so largely found in London.
3. Gauged brickwork, Plate II., fig. 1. Sometimes whole fronts are built in this manner, but usually piers, panels and dressings. The bricks are rubbed exactly to one size and perfectly smooth on face, with sharp arrises, and they are built with very thin joints ( $\frac{1}{8}$  or  $\frac{1}{16}$  in.) with lime-putty for mortar. If judiciously employed such brickwork has very high value. Its application may be seen in the portion of a pilaster in Plate II., fig. 5. The earliest gauged work (gauged-measured) in England is about 1630. Plate II., fig. 1, of a window and pilasters at Kew Palace, is dated 1631. The work is gauged but not with that fine accuracy shown in the capital and wall behind in Plate II., fig. 6, which is from an example which represents the highest attainment yet achieved in this kind of brickwork.

**Joints and Pointing.**—Stronger and better work is obtained by leaving a rough flush joint or by striking a joint with the trowel at the time when bricks are laid than by raking out joints  $\frac{1}{2}$  in. and pointing afterwards; though the latter course ensures a more regular and even appearance. For the Tudor type of brickwork, Plate II., fig. 7, the mortar of joints should be left full and squeezed out by pressure when laying the bricks. The superfluous mortar will fall off itself under influence of the weather, leaving a natural surface. If there is any cement in the mortar, or if for any reason a more formal joint is required, the weather-struck joint is best. This is a method which makes the bricks of the upper course throw a slight shadow and water does not lodge on the lower course as when struck the wrong way. Also, when wrongly struck, water penetrates above the joint which frost disintegrates. Old brickwork may have to be re-pointed. When this is necessary, the joints should be raked out much deeper than  $\frac{1}{2}$  in., which is usual,  $1\frac{1}{2}$  in. is not too much. Objection is sometimes taken to the struck joint for repointing 18th century type of brickwork, where the edges of bricks are worn and broken and where it is desired the wall face should present a neat and formal appearance. In such circumstances tuck pointing is employed, for which the raked-out joints are pointed flush with the wall face in cement or lime mortar and the whole coloured evenly with copperas and coloured pigment, or the whole wall is rubbed over with a piece of soft brick to the colour required. White lime putty or black stopping is then applied to a fine joint which has been raked out in the new mortar and by means of a straight edge and jointer and trimming with a frenchman (a table knife with the point turned up at right angles) a white joint

$\frac{3}{8}$ in. wide and projecting  $\frac{1}{8}$ in. is formed. Recessed, keyed, bastard-tuck, and other joints are seldom used now and are not to be recommended.

**Hollow Walls.**—Fig. 4 shows a section of a small country house built with hollow external walls, instead of a solid wall. Two  $4\frac{1}{2}$ in. walls are built  $2\frac{1}{2}$ in. apart and are tied together with wrought iron metal ties. The effect is that only the outer wall is exposed to wet, the air in the cavity acts as a non-conductor and consequently the inner wall is warm and dry. Various forms of iron ties are made and some architects prefer glazed brick ties, but the iron ties are most used. At least two are built into every super yard and one to every 12in. height at openings. The section shows the usual practice of brick construction. On the concrete foundation are the stepped footings of brick. Under the floor is a layer of concrete, on which are the sleeper walls, consisting, in this case, of two courses of brick  $4\frac{1}{2}$ in. wide, between which the damp-proof course of the inner wall is continued across to the wall on the other side of the house. On these sleeper walls the floor joints rest. Moisture passing through the outer wall falls to the bottom of the cavity and is prevented soaking inwards or upwards by the damp-proof course. Openings at the sides of windows are sealed with pieces of slate in cement. Over the windows sheet lead is built into a joint of the outer wall and carried upwards across the cavity into a joint one course higher up in the inner wall. This prevents moisture from the wet brickwork soaking down through the woodwork of the windows. The cavity is ventilated by air inlets passing through the outer wall. It is important that no fragments of mortar should be left which would bridge the cavity, for they would conduct moisture to the inner wall. Such 11in. hollow walls are more stable than gin. solid walls because they have a broader base but would not be permitted in London as substitute for the latter, so that there a  $4\frac{1}{2}$ in. outer and a gin. inner wall would be required. Hollow walls effect economy in expensive facing bricks, as common bricks can be used for the inner wall and only half the number may therefore be required for the half brick outer wall.

**Arches.**—Any arches that are built in stone may be carried out in brick (*see ARCH*), but the forms most used are segmental, semi-circular and straight. The segmental and many semi-circular arches are built of ordinary bricks (not *voussoirs*), the difference between the curves of *extrados* and *intrados* being taken up in the joints, which are wedge-shaped. Other semi-circular arches are carefully gauged. Straight arches (which must be built of gauged *voussoirs*) used over window and door openings are better built with a slight rise. Even a  $\frac{1}{2}$ in. rise in a 3ft. opening avoids the appearance of a sagging lintel, which is not only unpleasing but may cause fracture of the arch in course of time should the mortar have slightly deteriorated. Even a slight rise increases the strength.

**Corbelling and Chimney Caps.**—The projection of brick corbelling is limited by (i.) the thickness of the wall—but equal corbels on each side of a wall will balance each other—and by (ii.) the tailing-in (the securing of the wall end of a brick). For excessive projection, as for brick cornices, extra long bricks may be

specially made, but skilful men work wonders with bricks of ordinary dimensions, as in the cornices above and below the window in Plate II., fig. 1.

A common form of corbelling is in construction of chimney caps, of which an infinite number of well designed old examples exists. With thin bricks and a large shaft, projections may be as much as or more than  $1\frac{1}{2}$ in. each course. If the shaft is slight or if the bricks are thick,  $\frac{3}{4}$ in. projection may be too great. The old builders seem to have worked less by rules than by trial and experience, and until a cap has been proved satisfactory on a shaft of certain proportions it is wise to proceed in the same way and see at least half a cap built up as a trial. The profiles given in fig. 1 are all of old caps. Plate II., fig. 2, shows a 16th century chimney having detached, octagonal shafts.

**Chimney Breasts and Flues.**—The isometric drawing, fig. 5, shows the treatment of these on each side of a  $1\frac{1}{2}$  brick party wall between two houses. The descriptive lettering is self explanatory.

Brick fireplaces are more in keeping with the "farmhouse" type of room than in association with highly finished interiors, such as panelled rooms, white-painted woodwork, and dainty wall-papers. It is questionable whether bricks used for fireplaces should be smaller than  $7 \times 3\frac{1}{4} \times 1\frac{3}{4}$  inches. The effect of very small bricks and of patterns worked with pieces of plain tile is too finicky and restless to be satisfactory.

**Gauging, Moulding, Cutting, and Carving** are the higher branches of the bricklayer's art; mastered by few, though many attain some skill in the first three. Allusion has been made already to gauged work, for which bricks are cut with hammer and bolster (a heavy chisel) or with a saw (the blade of which is formed of twisted steel wire stretched in a frame) and finished on a rub stone of coarse, sharp sandstone. Special bricks, called rubbers, are generally used. They contain a large proportion of sand and are easily worked. Much of the moulded work in Tudor times was cut by hand ("axed" was the term, because the brick axe, now obsolete, was the tool employed) and ordinary bricks were picked over to find those which were, not soft, but less hard than the bulk of a making. The method of working varies with the nature of the design. A template (pattern outline) is first made out of card or a thin piece of wood. This is laid upon the brick to be cut and its outline scratched in deeply. The superfluous portions are then cut off (working from outside inwards) with the scutch, which is a light hammer having chisel-shaped heads which can be changed. Some skill is required to get round pieces of stone which have been incorporated in the brick and examination of old moulded bricks shows how the cutter worked. If necessary the work is finished off with a rasp, but a good workman, now, as in Tudor times, will finish his work with the chisel-edged tool. The window in Plate II., fig. 4, has all its moulded bricks cut by hand. The treatment of the intersection of transom and mullions is particularly interesting. Bricks for cutting should not be made with frogs, for often the cutting will expose the cavity. Even a simple mullioned window may require a dozen different templates and as many shaped bricks to be cut. Where there are many windows or where large numbers of each brick are required, it pays to have the bricks "purpose-moulded" in specially made moulds by the brick-makers, but these never have quite the same quality of form and texture as when cut by hand. During the 16th century many chimney shafts were constructed of circular and octagonal sections, embellished with spirals in great variety and with diapers of many patterns, some in purpose-moulded brick but most cut by hand.

**Brick Carving.**—This is rarely done now, yet it is easy and decorative. The practice is to build up a block of soft (rubber) bricks with very thin joints and to carve the completed block *in situ*. The arms of Henry VIII. are carved over the archway of the gatehouse at East Barsham Manor House, where, however, the brick is in lumps four courses high. Plate II., fig. 1 shows carved Ionic capitals and a carved keystone to the window arch, while Plate II., fig. 6, is of a beautiful Corinthian capital of gauged brick carved. Modern work is less ambitious but has taken the form of swags of fruit or flowers, cartouches (bearing a monogram or date), and other enrichments commonly associated with stone.

FIG. 5.—EXAMPLES OF CHIMNEY BREASTS IN PARTY WALL

**Diapers and Patterns.**—These were favourite devices of French builders of the 15th century, the patterns in various coloured bricks being derived from the mediaeval Italian work and their influence is seen in contemporary buildings in England, though not equally varied. Fig. 2 shows some French examples. There was a revival of this use of dark headers in 18th century brick buildings in England, usually by picking out the headers which had grey ends and building these so as to produce horizontal or vertical bands. Also by building all headers in Flemish bond, an evenly chequered wall surface was produced. Such restricted methods were often pleasing and more satisfactory than the florid 15th and 16th century treatment. The secret of good results in the use of grey headers is to pick out and use only the soft greys, not the very dark ones. The effect of the latter may be seen in the school buildings at Rugby, which no one would wish to imitate. Strap-work as shown in the panel Plate II., fig. 3, is another excellent form of pattern making.

The nature of bricklayer's work varies from the roughest walling to that requiring great care, but in estimating for any work it has always been necessary to compute what a man should produce. The compilers of old price books based their figures on what a man would average on ordinary house building, taking one kind of work with another but excluding special works such as gauged work, tuck pointing and fancy work. Men were expected to erect their own scaffolding in the time reckoned, and the working day was ten hours.

In 1667, 1,000 bricks daily for one bricklayer and his labourer.

In 1703, 1,000 do. do. do.

1,200/1,500 by exceptional men.

1734 as in 1703.

1749, 1,000 bricks daily for one bricklayer and his labourer, 1,500 if all work was common, rough walling.

1835, 1,000 bricks daily for one bricklayer and his labourer. The modern equivalent, for an eight-hour working day, should be 800 bricks daily.

As many as 809 bricks were laid by one man in an hour at Treeton, York, in 1924, and at Rotherham, in April 1927, William Milnes, a foreman bricklayer, laid 1,121 bricks in one hour—a record not likely to be broken. The work was of the rough kind, which writers quoted above reckoned should be done at the rate of 1,500 daily. Such concentrated effort, assisted by materials being placed by a staff of labourers, bears little relation to daily work but does suggest that, given bricklayers having the will to do more, much might be done to assist output by arranging work and materials conveniently. Detail photographs of the actual operations show the work to have been done from scaffolding and to have been sound and good, as indeed competent eye-witnesses certified it to be; 700 bricks daily is the usual output in the district.

Lloyd, *A History of English Brickwork* (1925), although a complete record of brickwork to the end of the Georgian period, it is so fully illustrated as to be comprehensible by any layman; M. B. Smith, *Italian Brickwork* (1929); B. Langley, *The London Prices of Bricklayers' Materials and Works* (1749), full of information about methods still practised. (N. L.)

**BRICOLE** (a French word of unknown origin), a military engine for casting heavy stones; also a term in tennis for a side-stroke rebounding off the wall of the court (corrupted into "brick-wall" from a supposed reference to the wall), and in billiards for a stroke off the cushion to make a cannon or hazard.

**BRIDE**, the term used of a woman on her wedding-day. It appears in many combinations, some of them obsolete; e.g., "bride-bell" (wedding-bells), "bride-banquet" (wedding-breakfast). The bride-cake, or wedding-cake, had its origin in the Roman *confarreatio*, a form of marriage, the essential features of which were the eating by the couple of a cake made of salt, water and flour, and the holding by the bride of three wheat-ears, symbolical of plenty.

In the middle ages the wheat-ears were worn or carried by the bride. It became the custom for young girls to assemble outside the church and throw grains of wheat over the bride. In time the

wheat-grains were cooked into thin dry biscuits, which were broken over the bride's head. In Elizabeth's reign these biscuits took the form of small rectangular cakes made of eggs, milk, sugar, currants and spices. Every wedding-guest had at least one, and the cakes were thrown at the bride as she crossed the threshold. They were the forerunners of the modern wedding cake which assumed its glories of almond paste and ornaments during Charles II.'s time.

Even to-day in rural parishes, wheat is thrown over the bridal couple with the cry "Bread for life and pudding for ever," expressive of a wish that the newly wed may be always affluent. The throwing of rice, a very ancient custom but later than the wheat, is symbolical of the wish that the bridal may be fruitful. The *bride-cup* was the bowl or loving-cup in which the bridegroom pledged the bride, and she him. The phrase "bride-cup" was also sometimes used of the bowl of spiced wine prepared at night for the bridal couple. *Bride-favours* (or bride-lace) were at first pieces of gold, silk or other lace, used to bind up the sprigs of rosemary worn at weddings. Later these took the form of bunches of ribbons. *Bridegroom-men*, or groomsmen, represented a survival of the primitive days of marriage by capture, when a man called his friends to assist to "lift" the bride. Bridesmaids were usual in Saxon England. The senior of them attended the bride for some days before the wedding. The making of the bridal wreath, the decorations for the wedding-feast, the dressing of the bride, were among her special tasks. The senior groomsmen (the best man) was the personal attendant of the husband. The *bride-wain*, the wagon in which the bride was driven to her new home, gave its name to the weddings of any poor couple, who drove a "wain" round the village, collecting small sums of money or articles of furniture towards their housekeeping. These were called *bidding-weddings*, or *bid-ales*. In Wales so general was the custom of "bidding-weddings" even up to the early part of the present century that printers kept the form of invitation in type. The bride's veil is the modern form of the *flammeum* or large yellow veil which completely enveloped the Greek and Roman brides during the ceremony. Such a covering is still in use among the Jews and the Persians.

**BIBLIOGRAPHY.**—See Brand, *Antiquities of Great Britain* (Hazlitt's ed., 1905); Rev. J. Edward Vaux, *Church Folklore* (1894).

**BRIDEWELL**, a district of London between Fleet Street and the Thames, so called from the well of St. Bride or St. Bridget close by. From William the Conqueror's time, a castle or Norman tower, long the occasional residence of the kings of England, stood there by the Fleet ditch. Henry VIII., Stow says, built there "a stately and beautiful house," specially for the housing of the emperor Charles V. and his suite in 1525. In 1553 Edward VI. made it over to the city as a penitentiary, a house of correction for vagabonds and loose women. Owing to this circumstance, other institutions of this character were frequently known as bridewells in England and sometimes also in the United States.

**BRIDGE.** The origin of the game of Bridge is very doubtful. It is sometimes said to have originated in Russia, but there is no satisfactory proof of that statement. It was first known under the title of "Biritch, or Russian Whist," and this probably gave rise to the idea that it was of Russian origin, although, as a matter of fact, the word "Biritch" is not to be found in any Russian dictionary. Many years ago the Russians played a card game called "Ieralasch," or "Ieralache," which bore a close resemblance to short whist without a trump suit. From this arose the more scientific Russian games of "Siberia" and "Preference," both of which had certain points in common with Bridge.

There is no record of the transformation of any of these Russian games into anything approaching modern bridge. The game was probably of Levantine origin. It was certainly played 50 years ago in Eastern Europe, notably in Constantinople and in Greece, and, if there were any necessity to assign to it a definite nationality, that honour must be awarded to Greece. There has been a good deal of correspondence in the newspapers as to the origin of the name "Bridge," and some very fantastic reasons have been given for it, but the transition from "Biritch" to "Bridge" is such a very natural one that it is surely unnecessary to look any further.

It is an old story how Lord Brougham, who had recently returned from Cairo, went into the card room of the Portland club one afternoon in the autumn of 1894, and sat down to play whist. When it came to his turn to deal he omitted to turn up a trump card, and when his attention was called to it he said, "I am very sorry, but I thought I was playing Bridge." "Bridge," they said, "what is that?" "What a pity you do not know it," he replied, "it is the finest card game ever invented." As soon as the rubber of whist was finished the others asked him to show them this wonderful new game. He did so, and they were so charmed with it that, from that moment onwards, bridge became the standard game at the Portland club, which had always been regarded as the headquarters and the stronghold of whist. From the Portland club the new game soon spread to other clubs, and wherever it was introduced there it stayed and flourished, so that in a very short time it became practically the national card game of Britain. The idea that bridge was unknown in Britain till then is mistaken. It was unknown in London clubland, but it was regularly played, in private circles, many years before.

It has been stated that the game was first introduced into Britain in 1880, but there is no evidence of that. The first authentic mention of it is that, in the year 1886, a small pamphlet was published in London, entitled "Biritch, or Russian Whist." It was quite a small affair, giving a very attenuated description of the game, but what there was of it, the method of scoring, and the laws as to declaring, etc., were almost identical with bridge which came into vogue eight years later. There is a copy in the British Museum (Press mark 7913 aa 51), and another in the Bodleian, and there are said to be one or two in private hands.

For a considerable time after the introduction of bridge in 1894, it remained almost exclusively a club game. Men played it at London clubs, or in their country houses when they were able to get up a rubber, but it was by no means the popular social game which it has since become. It was not until the beginning of the present century, in 1901 or 1902, that ladies discovered what a delightful field of amusement and speculation was open to them. When once they realized the fascination of the game they adopted it as their own, and became even more enthusiastic about it than the men. There are many first-class women players. London is full of mixed bridge clubs, and there are many for women only.

Whist and bridge are somewhat on the same lines. Both are partnership games for four players, and the play of the cards is on similar lines, but there are two outstanding points of difference. First, as to the trump suit. At whist this is arbitrarily determined by the last card dealt, which the dealer turns up on the table. At bridge the trump suit is selected by the dealer or his partner, without consultation, or they can elect to play without a trump (*sans atout*). The other point of difference is that, although there are four players, the dealer's partner is always dummy, and takes no part in the play of that particular hand. Directly the first card is led, dummy's cards are exposed on the table, and the duty of playing the two hands devolves solely on the dealer. The value of both tricks and honours varies with the trump suit. The game consists of 30 points scored by tricks alone. The score has to be kept on paper. For this purpose scoring blocks are provided with two vertical columns divided by a horizontal line. Tricks are scored below the horizontal line and honours above. The score for honours does not count towards winning the game, but as soon as the score of either side amounts to 30 or more, below the line, the game is won. At the end of the rubber the whole score, above and below, is added up, and 100 points are added to the winners of the rubber. A rubber is the best of three games. If the first two are won by the same side the third is not played.

Declarations can be doubled by the adversaries and redoubled by the declarers, but not beyond the point at which each trick is valued at 100. Doubling does not affect the score for honours on penalties. Each trick above six ("the book") counts:—

- When spades are trumps, 2 points per trick.
- When clubs are trumps, 4 points per trick.
- When diamonds are trumps, 6 points per trick.
- When hearts are trumps, 8 points per trick.
- When there are no trumps, 12 points per trick.

Honours consist of ace, king, queen, knave, ten in a suit declaration, and the four aces when there are no trumps.

If a player and his partner conjointly hold any three suit-honours they score twice the value of the trick; if four honours, four times the value; if five honours, five times the value. If a player holds four or five honours in his own hand, he scores eight or ten times the value of the trick, and if when a player holds four his partner holds the fifth they score nine times the trick value above the line. In a no trump game three aces in the joint hands count 30, four aces count 40, or four in one hand 100 points.

On the completion of the deal, the dealer must either make a declaration or leave it to his partner. A declaration means that the declarer contracts to win at least the odd trick in a specified suit, or at no trumps. When the declaration is left the partner of the dealer is obliged to declare something—he has no alternative. If he has a bad hand, he will naturally declare spades, as that is the cheapest declaration he can make. If he has a good hand, he will declare no trumps. Whatever he declares the dealer will play the two hands; the partner will put his cards down on the table and become dummy. Whichever side wins the odd trick or more scores the value of it below the line. It is quite possible for the adversaries to win the game on a declaration by the dealer.

The declaration at bridge affords an opportunity for the exercise of certain qualities which were never called into use in the game of whist. The same technical skill is required for the management and play of the cards in both games, but at whist the trump suit is fixed before the start, whereas at bridge the result of the game will frequently depend upon the judicious exercise of the right of choosing the trump suit. The most expensive declaration being no trumps, when the value of each trick is 12 points, or more than a third of the game, the first consideration of the dealer should always be whether his hand is strong enough for this call. The game of bridge owed a great part of its popularity to the no trump declaration. There is nothing quite like it. It was, of course, unknown at whist, which, towards the finish, became almost more of a science than of a speculative game, but here you have a strong element of uncertainty and speculation, which appeals strongly to the mind of the average player, and also it is so much more interesting to play the combined hands at no trumps than in a suit declaration.

The game of bridge had a great success in Britain for rather more than ten years, and then, just as suddenly and completely as it had killed whist, it was itself superseded by its own offspring, auction bridge. (See AUCTION BRIDGE; CONTRACT BRIDGE.)

(W. DA.; X.)

See also W. Dalton, *Bridge Abridged, or Practical Bridge* (1901); J. B. Ellwell, *Advanced Bridge* (1904).

**BRIDGEBUILDING BROTHERHOOD**, a confraternity (*Fratres Pontifices*) that arose in the south of France during the latter part of the 12th century, and maintained hospices at the chief fords of the principal rivers, besides building bridges and looking after ferries. The brotherhood was recognized by Pope Clement III. in 1189.

**BRIDGE-HEAD** (Fr. *tête-du-pont*), in fortification, a work designed to cover the passage of a river by means of fortifications on one or both banks. In a wider sense it is used to mean the area occupied on the far side of a river by a protective detachment in order to cover effectively the crossing of the main body. As the process of moving an army over bridges is slow and complicated, it is usually necessary to secure it from hostile interruption, and the position constituting the bridge-head must therefore be sufficiently far advanced to keep the enemy's artillery out of range of the bridges. In addition, room is required for the troops to form up on the farther bank. In former days, with short-range weapons, a bridge-head was often little more than a screen for the bridge itself, but modern conditions have rendered necessary far greater extension of bridge defences.

**BRIDGEMAN, WILLIAM CLIVE** (1864– ), British politician, was born in London Dec. 31 1864, and educated at Eton and Trinity college, Cambridge. He was elected Conservative member for the Oswestry division of Shropshire in 1906. He was a junior lord of the Treasury in the first coalition Government

and afterwards assistant director of the war trade department. Under Mr. Lloyd George he became successively parliamentary secretary to the Ministry of Labour (1916) and to the board of trade (1919) and was secretary of the mines department (1920–22). In 1923 he became an ecclesiastical commissioner. In the Conservative ministry of Mr. Bonar Law and Mr. Baldwin he was home secretary. His action in ordering the deportation and internment in Ireland of Irish prisoners in England was declared illegal by the court of appeal, and an Indemnity bill was passed for his protection. Having become, in Nov. 1924, first lord of the Admiralty in Mr. Baldwin's second ministry, he revived the proposal for establishing a dockyard at Singapore. He was created a Viscount on June 3, 1929.

**BRIDGEND**, urban district, Glamorganshire, Wales, on both sides of the River Ogwr (whence its Welsh name Penbont-ar-Ogwr). Pop. (1931) 10,033. The town is an old agricultural centre on the fertile plain of south Glamorgan, and like most bridge settlements, it seems to have grown up in two parts—Newcastle on the west and Oldcastle on the east of the river. In Newcastle there are ruins of a 12th century Norman castle. The proximity of the high ground of central Glamorganshire made the town that grew around the bridgehead nuclei a market centre where the produce of the hills could be exchanged for that of the plain, and where, in the last century, the mining population of the Llynfi, Garw and Ogwr valleys gathered to purchase their weekly provisions. The town has a tannery and brewery, and there are brickworks and stone quarries, and much lime was burnt in the neighbourhood. The growth of Maesteg limited Bridgend for a time, but the recent growth of road traffic is tending to help Bridgend once more.

There was no civil parish of Bridgend previous to 1905, when one was formed out of the parishes of Newcastle and Coity. The town is now in the Ogmore parliamentary division. It has a station on the G.W.R. main line as well as connections with Barry, and the Llynfi and Garw valleys.

**BRIDGE OF ALLAN**, police burgh, Stirlingshire, Scotland. Pop. (1931) 2,897. It lies on the Allan, a tributary of the Forth, 3m. N. of Stirling by the L.M.S. railway and by tramway, on the wooded slopes of Westerton and Airthrey hill, sheltered by the Ochils from north and east winds. There is a pump-room and the Macfarlane museum of fine art and natural history. The industries include cotton manufacture and paper-making. The Strathallan gathering, usually held in the neighbourhood, is the most popular athletic meeting in mid-Scotland.

**BRIDGEPORT**, the leading manufacturing city of Connecticut, United States, and one of the important industrial centres of the country, on Long Island sound, at the mouth of the Pequonnock river, about 60m. N.E. of New York city; a port of entry and the county seat of Fairfield county. It is served by the New York, New Haven and Hartford railroad and by coasting steamers. A municipal airport is under construction. The area is 18.4 sq. miles. The population in 1920 was 143,555, of whom 46,414 (32%) were foreign-born white, including large numbers from southern and eastern Europe; in 1930 it was 146,716.

The city has a delightful location. Beardsley park (150ac.) contains beautiful rustic scenery; and Seaside park extends nearly 3m. along the sound. A city plan was prepared in 1916. There is a good natural harbour, formed by the estuary of the river and two inlets called Yellow Mill pond and Black Rock harbour. The commerce of the port in 1925 amounted to 1,016,881 tons, valued at \$98,630,759. About 90% is incoming tonnage, of which considerably over half is coal, coke, and fuel oil, and most of the rest is pig-iron, scrap-iron, copper, sand, clay, lumber and other materials required by the manufacturing industries. The 329 factories within the city in 1925 had an aggregate output valued at \$149,098,353—about 12% of the total for the State. Among the most important manufactures are firearms and ammunition, sewing machines, corsets, gramophones, motor-vehicle bodies and parts, electrical machinery and apparatus, chain goods, plated ware, bronze, brass, iron, steel and numerous articles made of these and other metals. The assessed valuation of property in 1926 was \$232,423,371.

The first settlement here was made in 1639. It was called Pequonnock until 1701, and then Stratfield. The borough of Bridgeport was incorporated in 1800; the town in 1821; the city in 1836. During the Revolutionary War it was a centre of privateering. P. T. Barnum, the showman, lived here after 1846, and did much for the improvement of the city. For many years it was the winter headquarters of Barnum and Bailey's circus and of Buffalo Bill's Wild West Show. Elias Howe built a large sewing machine factory here in 1863. During the Civil War the city made trainloads of coats, fire-arms, and other supplies for the army, and in the succeeding decade it developed into an important manufacturing centre, with a population in 1880 of 27,643, which increased to 102,054 by 1910.

At the outbreak of the World War large orders were received from the Allies for firearms, ammunition and other articles. Within two years (1914-16) the population increased 50%. Congestion in dwellings, schools, streets and trolleys became serious and there were numerous strikes. Production included 2,000,000,000 cartridges, 1,218,979,300 rounds of ammunition, submarines, Browning guns, automatic rifles, anti-aircraft guns, projectiles, target shells, naval guns, and copper bullets. After the Armistice the industries readjusted themselves to normal demands; the excess supply of labour disappeared; and construction of houses and schools was able to overtake the increase of population. In 1927 the population was estimated at 170,000.

**BRIDGES, CALVIN BLACKMAN** (1889- ), American genetician, was born at Schuylers Falls, N.Y., on Jan. 11, 1889. In 1912 he graduated at Columbia university where in 1916 he received the degree of doctor of philosophy and was research assistant to T. H. Morgan during 1910 to 1915. From 1915-19 he continued his researches under grants from the Carnegie institution, of whose staff he became a member in the latter year. The chromosome theory of heredity and sex determination engaged his particular attention.

His publications include *The Mechanism of Mendelian Heredity* (1915); *Sex-linked Inheritance in Drosophila* (1916); *Genetics of Drosophila* (1925) and a number of papers.

**BRIDGES, ROBERT** (1844-1930), English Poet Laureate, born at Walmer Oct. 23, 1844. Educated at Eton and Corpus Christi College, Oxford he afterwards studied medicine and became Consulting Physician at the Children's Hospital, Great Ormond Street, and assistant Physician at the Great Northern Hospital. In 1882, at the age of 38, he abandoned medicine. *Prometheus the Fire-Giver*, published in 1883, could appeal to few but scholars. Eight plays, *Nero* (part I), *Palicio*, *Ulysses*, *The Christian Captives*, *Achilles in Scyros*, *Humours of the Court*, *The Feast of Bacchus*, *Nero* (part II) were issued between 1885 and 1894. *Demeter*, a mask, was written for the undergraduates at Somerville College, Oxford, and acted by them in 1904.

Dr. Bridges is to be found in a still more experimental vein in the poems in classical metre which he began to publish in 1903. There has never been an English poet, indeed, who has been more interested in prosody. In the lyrics collected in *Shorter Poems* (1890) he had fortunately shown that poetry was for him something more than a prosodist's laboratory. Here the artist takes control of the scholar, and genius makes use of new measures, not for their own sake, but in order to pour into them the pure treasures of inspiration. In lyric after lyric—"A Passer-by," "London Snow," and "On a Dead Child,"—the novelty of the form, remarkable though it is, does not distract us from the vision that it reveals. Many of the lyrics of Dr. Bridges express a joy in the lovely things of life so pure and unclouded that, as we read, it seems never to have been expressed before. Even though the shadow of death and sorrow falls at times on his verse, the general impression his work leaves on us is one of serene delight. In 1913 Mr. Asquith appointed him to the Poet Laureateship. Probably his anthology, *The Spirit of Man*, compiled during the War (1916), achieved wide popularity. His critical writings on poetry, language and pronunciation are both valuable and original, and he has written in the spirit of a reformer as a founder of the Society for Pure English. But his chief writings in prose are the two essays, *Milton's Prosody* (1887) and *John Keats, a Critical*

*Essay* (1895), and *The Necessity of Poetry, an Address* (1918). In *New Verse* (1925) he tried new metres. He was awarded the O.M., June 3, 1929. In 1929, at the age of 85, Bridges published his last great poem, *The Testament of Beauty*, an ardent confession of philosophical faith, written in "loose Alexandrine" metre, in which he aimed at reconciling scientific knowledge with traditional belief. Bridges died April 21, 1930.

**BRIDGES.** The function of bridges may be described as the starting of a stream of human traffic hitherto impossible; the surmounting of a barrier, the linking up of two worlds divided by a gulf. One such barrier, the great River Severn, has decided more than once the fate of England. Thus when Margaret of Anjou had crossed to England, just as Edward was disbanding the last of his infantry after Barnet, she attempted to reach Bath, with Edward pounding on out of Cirencester. From then until the battle of Tewkesbury her movements were those of a person who is being chased in the direction of a wall in which there is a gate she cannot find. And eluding, feigning, doubling back, she was brought to a standstill at last and crushed against the barrier she had so desperately striven to cross and could not. In the early hours of May 1, the king, having heard news of her westward march, "toke advise of his counsell of that he had to doe for the stopynge of theyr wayes, at two passagys afore namyd, by Glocestar, or els by Tewkesberye." It was not only that her men were completely exhausted after their march; not only that the king was only half-a-dozen miles behind her, "evar redy, in good array and ordinaunce"; but at Tewkesbury the river became two rivers, and having failed to cross thus far, how could she hope to do so thereafter? With the Severn on its right, and the Avon on its left, her army could only stand still and await the death-blow.

Another drama of the same kind, and even more striking though it ended not in massacre but in withdrawal by sea, was set on the banks of the Chickahominy in Virginia during the American Civil War. After long delays General McClellan had succeeded in carrying his plan for an attack on Richmond. When at last his army had been transported to the peninsula it took two more months before they reached the Chickahominy. During that time the rebels had gathered thousands of recruits and an army of slaves was at work on entrenchments. Already the attack was weeks overdue; every moment wasted increased the exhaustion of the Northern troops and added to the enemy's strength. But for the

THE BRIDGE OVER THE RIVER SHANNON AT ATHLONE, IRELAND

Chickahominy, Richmond might still have been taken and the subsequent history of the Civil War might have been shorter and very different. Instead, the army, during another disastrous month, lay astride the river, unable finally to cross to this side or that, its ranks daily thinned by malaria and by the unaccustomed heat. If the whole of the men were brought across to the south bank the line of communication with Washington would be imperilled and the stores laid down further north almost certainly destroyed. Yet the army was too small to march on Richmond and leave a guard behind, while to have remained on the north bank would

have been at once to acknowledge failure and defeat. Caught in the toils of the Chickahominy it could neither advance nor retreat, and all the while the men knew that nothing could be more perilous than the immobility into which they were forced by their enemy, the unbridged river. The lines extended 20 miles on either side; and it is true that six or seven dilapidated bridges united them. But six or seven were not enough, and though other bridges were begun in the few places where a crossing seemed approachable, McClellan's troops could never build so many that their movements would become rapid and secure. And so they were held until their danger became too great and began to close round them on every side, so that they had to fight their way out of the trap into which they had so innocently wandered.

The frustration of Margaret's plans was due in part to the immediate action taken by the king, who turned the Severn into his most powerful weapon against her; the Chickahominy did its work unaided, which may explain how the escape of the imprisoned armies was made possible. When man and nature work in alliance the result is usually more certain. The entrapping of Simon de Montfort at Evesham could only have been contrived by a man completely familiar with the River Avon and its bridges and determined to use both the one and the other to their utmost capacity. With half his army Prince Edward came rushing back from the disabling of young Simon at Kenilworth while the other half marched from Worcester in time to meet him at Evesham; and in order to make sure against Simon's escape, each half divided again at carefully arranged points and united, the one at the next bridge upstream (a couple of miles away) and the other at Evesham itself, the duke of Gloucester's division rejoining the northern forces by crossing Evesham bridge from the south. In this skilfully planned manoeuvre the Avon crossings were played against Simon as a hand at cards is played, one crossing after another being used and guarded like the opening and shutting of so many doors, and thus made to contribute to the cumulative result that meant a sudden and decisive victory.

**Old Bridge Construction.**—The history of all old bridges which have survived complete is one of almost continuous repairs, and the written records that remain tell us of the unceasing labours of those who raised funds for their maintenance. Without such vigilant care no masonry bridge, no matter how well built, was likely to last much over a century. Storm and flood, sun and frost, combining with the vibration of traffic, found a weak point somewhere, and, unless the damage was repaired at once, it spread with startling rapidity. True, in the middle ages, when the foundations of a stable civil government were only gradually being laid, builders made every effort to lessen the need for future repairs by designing their bridges so that an injury would not spread quite so quickly. The piers were so heavily constructed that every arch rested in what was virtually an isolated compartment. But this device brought other dangers and drawbacks, to which some reference must presently be made.

The pounding of horses' hoofs above and of angry waters below were enemies above all to be dreaded. It is easy, when we consider these, to understand why the most perfectly preserved and hence the most celebrated of all Roman bridges in Europe should be not bridges properly speaking, but the aqueducts that carried their water supply across a valley. Many of the so-called Roman bridges in all parts of Europe are not Roman bridges at all. Of the four in Rome itself, not one contains any masonry that can with confidence be dated earlier than the beginning of the 15th century. A ruin such as the beautiful single arch over the Tiber at Narni, 50 m. from Rome, is much more likely to contain original stones.

**English Bridges.**—English bridges have hardly received their proper regard, for the achievement they embody with such modesty is the result not of a single great effort but of centuries of unremitting labour; great though the effort of building a bridge may have been, it is as nothing beside the efforts required to maintain it. Towards the end of the 14th century, London bridge had attached to it a permanent building staff of a dozen carpenters and masons. Doubtless a great many more were recruited in special emergencies. The financial provisions which enabled these men to

be kept at work have made the Bridge House estates committee (the survival of a governing committee set up at the end of Elizabeth's reign) one of the wealthiest bodies of its kind in Europe. The first regular source of revenue enjoyed by London bridge were the rents of the houses and shops on the bridge, which in the 14th century amounted to £160 per annum and in the 18th century to five times as much. But tolls were already being levied on passengers, and landed property bequeathed to Bridge House was bringing in considerable sums; a lucky circumstance when we remember that in the last few decades of its long life the annual maintenance bill for Old London bridge was four thousand pounds. Other and smaller bridges did not present the same problem, but few of them were fortunate enough to be placed in the care of permanent officials at such an early date. Where no warden was appointed the responsibility had to be fixed somewhere by law, and mediaeval records are full of inquisitions and disputes on this point. The case of the Long bridge at Shoreham is typical. The bridge being in a state of dangerous decay, the tenant of the adjacent land (which belonged to the archbishop of Canterbury) was adjudged responsible, and the bailiffs sold his goods and chattels that the neglect might be made good. Most bridges, however, were the subject of some kind of contract with Church or Government which made such hardships less likely to befall a local citizen. The corporation of Berwick, for example, received £100 per annum from the Crown for the maintenance of Berwick bridge, which still survives. No single entry in the Scotch Exchequer Rolls occurs more often than the words *Ad Sustent.* (*Ad Sustentacionem*), under the name of a bridge. Since then, the age of modern local government has of course transferred all responsibility to local authorities.

**Gateway Bridges.**—Most bridges before the 18th century were furnished with a gateway which was built either on one of the piers of the bridge or at one of the approaches. These gateways had a fiscal as well as a military use, and were often flanked by a toll-house. Only one example remains in the United Kingdom to-day, that which sits astride the Monnow bridge at Monmouth. Our coaching forefathers found them a serious obstruction and it is surprising to find even this one left. The toll-house on St. Ives bridge in Huntingdonshire no doubt had a gate in its day, but it does not stand beside it now.

**Age of Bridges.**—So close is the connection between the general development of civilization and the development of its bridges that we can best tell the age of a bridge by measuring its girth of masonry. Sometimes, but not often, a bridge or part of a bridge has a date carved on it; more frequently there is some written record of building or repair work. Yet even where such records exist it is often impossible to say whether the date they give is that at which the foundations were put down and the arches first built. The gradual widening of the average span, and the gradual narrowing of the average pier, give us surer evidence of date. In the British Isles, as Harry Inglis has pointed out, the arches start from the neighbourhood of 25 ft., the average span of those of Old London bridge, about the year 1200, to reach a maximum of 75 ft. about the middle of the 18th century, when modern engineering had its birth, and since then the increase has progressed in width with startling rapidity. The obstacle that the bridge presents to the water's flow continually grows smaller, until the suspension bridge leaves next to nothing standing in its way.

**The Nodal Bridge.**—Among the various parts played by a bridge in human history there is one which is greater than any, and which strangely enough requires that traffic on the river should be considerably impeded. This is the part of what has been described as a nodal bridge. A nodal bridge is one which stands at the point where a busy water-way is crossed by a busy land-way in such a manner that the two streams of traffic are mixed together. Most of the great commercial centres of the world owe their expansion, if not their origin, to such a nodal bridge. It is safe to say that had there been no suitable site for a mediaeval bridge anywhere between Wapping and Charing Cross, London as we know it to-day would never have existed. Moreover, if by some impossible anachronism Old London bridge had been suspended from a

#### FOUR ARCHED BRIDGES IN ENGLAND

1. Monnow bridge, over the river Wye at Monmouth, said to date from 1272, the most perfect existing example of a bridge with fish and military tower and gate. These are shown on the bridge at the right of the picture
2. Richmond bridge, over the Thames at Richmond, designed by James Payne, and built in 1774, showing the five central arches of stone; the most famous of the classical Georgian bridges in England
3. Elvet bridge, over the river Wear at Durham, built by Bishop Pudsey in the twelfth century. It has ten pointed arches and is one of the few remaining bridges with a chapel upon them
4. Waterloo bridge, over the Thames in London, designed by Sir John Rennie and built in 1811, shown before the increased volume of motor transport caused a subsidence in the central piers

couple of piers as are several of the new bridges above Westminster, or if it had opened itself to waterborne traffic with as much ease as the bascules of Tower bridge, the Port of London would never have attained its present rank among the harbours of the world. It was necessary that ships should come in on the rising tide and be arrested by a bridge whose piers were so wide that they dammed up the Thames like a millrace. And it was also necessary that from this last navigable point there should run roads linking north with south across the Thames. The road was not a wide one, for when the great cross for St. Paul's dome was cast at Mitcham there was not room enough for it to pass. But it was a road nevertheless, and from its marriage with the river all London has been begotten.

The debt we owe to these nodal bridges is not easily remembered to-day, when they are flanked by many newcomers up and down the stream from which they are scarcely distinguishable. Now that Westminster has eclipsed London bridge in daily traffic utility and carries a flow of traffic almost equal to that in Regent street, London's busiest thoroughfare, who would guess from its appearance how very much less it has contributed to the life of London? A century ago, when London bridge still carried rather more than twice as much traffic as the busiest of its rivals, it would have told its own tale to the stranger; two centuries ago, when Westminster bridge was being built, all England was acutely conscious of the glorious record of its older neighbour. Ever since the time of Elizabeth, demands had been made for another bridge between Westminster and Lambeth. But the City of London, reinforced by the borough of Southwark (whose prosperity too depended on the same London bridge) and by various watermen's companies, set its face resolutely against the diverting of the precious human stream. There is a pamphlet dated as early as 1664 recording the angry views of the Lord Mayor and aldermen about the unborn rival. Not till nearly three-quarters of a century later was the act authorizing a new bridge approved by the parliament. This measure was the first stage in the westward movement of London which is going on undiminished to this day. Only a bridge could have started it. The opposition was no doubt due in some measure to the fact that London bridge was the Bond street of the time. A good three-quarters of the houses on the bridge were occupied by hosiers, hatters, glovers, haberdashers and other dealers in high-class apparel. But there was much more in it than this. It was the City itself that, remembering the manner of its begetting, found its supremacy challenged, if not (as perhaps it appeared at the time) its very existence. The City of London, being about to lose some of the benefits conferred upon it by its bridge, and thus in an excellent position to gauge those benefits at their full worth, saw at once that they were nothing less than the foundation of civilized human life.

See Walter Shaw Sparrow, *A Book of Bridges*; Christian Barman, *The Bridge* (1926); W. F. Watson, *Bridge Architecture* (1927); J. A. Waddell, *Bridge Engineering* (1916). (C. BA.)

**United States.**—Bridges have been of special importance in the development of the United States and Canada. In the early growth of the country the crossing of rivers was one of the greatest obstacles to be overcome by the pioneer. As recently as 50 years ago travellers in isolated districts often travelled long distances from their routes to cross a river by ferry or fording. Arriving at such a crossing, freezing weather or high water sometimes delayed them for weeks. In more recent years with the demand for speed, the development of railroad transportation and the growth of cities, bridges have become even more imperative. The most complicating factor, however, has been the tremendously increased demand for highway bridges, resulting from the great expansion in the use of motor vehicles. During 24 hours on four important bridges in New York city more than 2,600,000 persons pass in both directions across these structures afoot and on wheels. In America, where goods are transported greater average distances than in any other part of the world, bridge design is interpreted largely in the number of vehicles that can be accommodated per hour.

In consequence of this, many of the old bridges in the United States are being remodelled to meet the ever-increasing traffic demands.

The rejuvenation of many railroads beginning about 1920 and the great impetus given to bridge building by the increased use of highways, higher standards of living and the urge for greater commercial facilities between all sections of the country ushered in an era of bridge building that had not lost its momentum by 1928. In 1925 bridge-building contracts aggregating more than \$100,000,000 were let or projected. The Engineer Corps of the U.S. army has listed more than 5,000 bridges over navigable waters in the United States. Many of the newer bridges are owned and operated by private corporations, charging tolls, but with a limited or terminable franchise. In this way the immediate users pay for the construction and at the end of a definite number of years the State or contiguous districts become the owners of the property.

At or in the vicinity of large cities where a number of highways radiate from business centres into the surrounding country, bridges have become a prime necessity. A cross-section of a typical large city bridge would show that provisions are usually made for lines and "decks" for automobile traffic, railways, street-cars and pedestrians. Several of the important industrial communities have a dozen or more bridge projects under way. Manhattan island, closely riveted to that portion of New York State which lies to its east, is endeavouring to restore an unbalanced development of the metropolitan area by new bridges to the equally proximate section of New Jersey on the west. The great Hudson river bridge under construction between Ft. Washington on Manhattan island and Ft. Lee in New Jersey, with a suspended span of 3,500 ft., and being erected at a cost of more than \$50,000,000 epitomizes the effort that is being made on a small scale by nearly every American city whose natural water barriers are impediments to expansion and easy transportation. San Francisco, long a city with a bottle neck, is breaking the grip of adverse geography by planning a series of projects that will eventually link the city and its environs by bridges. The Carquenez strait span, completed in 1927, is one of the important steps in this plan.

Of ever-growing importance is the aesthetics of bridge design. More than 300 city-planning bodies have been established in various communities, and bridge engineers occupy prominent places in their councils. As conspicuous objects at the entrance to a city most bridges recently constructed have been influenced by landscape and topography and have been designed with regard to the factors of silhouette, mass and proportion. Typical of beautiful bridges in America is the Arroyo Seco at Pasadena, Calif., the Tempe bridge, Arizona, the Beechwood avenue bridge at Pittsburgh, Pa., the Cappelen Memorial bridge at Minneapolis, Minn., and the Brooklyn bridge at New York city.

Bridge architecture may be divided into five distinct types depending on the compressive strength or resistance of the material.

BY COURTESY OF MESSRS. ROBINSON AND STEINMAN  
THE CARQUENEZ STRAIT BRIDGE. 4,482 FT. LONG, BUILT OVER CARQUENEZ STRAIT IN THE BAY OF SAN FRANCISCO, 1927

Each of these types, the simple beam, cantilever, simple truss and the suspension, reflects an aesthetic counterpart. The simple beam has unusual artistic possibilities, as is seen in many American rural districts, and occupies a prominent position in landscape architecture.

The arch bridge is constructed of masonry, concrete or steel. Masonry bridges, massive and formed by one or more circular, elliptical or segmental arches need little architectural embellishment. Many such bridges in America have been patterned after the graceful mediaeval bridges in France and Spain. The longest

stone arch bridge in America is the Cabin John, near Washington, D.C., which has a span of 220 feet. The Arlington Memorial bridge, planned for completion about 1930, leading from the Lincoln Memorial in Washington, D.C., across the Potomac river toward the Arlington mansion in Virginia, will be architecturally one of the finest granite arch bridges in the world. It is to have nine arches and one steel bascule span. The spans will each be between 165 and 188 ft., and the project of which the bridge is a part will cost about \$14,000,000. Another interesting example is the granite arch bridge over the Connecticut river at Hartford, Conn., with a span of 119 feet.

Concrete, plain or reinforced, has been utilized for both cantilever and arch construction. The latter type has been more widely used, since the use of concrete is best adapted to short spans. The longest concrete arch bridge in the world is the Cappelen Memorial structure at Minneapolis, Minn., which has a span of 400 feet. In line and mass, concrete construction gives the appearance of thin masonry and shows an artistic expression quite distinctive from that of masonry or steel. Other American concrete arch bridges of note are found at Springfield, Mass.; Pittsburgh, Pa.; Fairmont, W.Va.; St. Paul, Minn.; Portland, Ore.; Spokane, Wash.; New Orleans, La.; Ft. Snelling-Mendota, Minn. Arch bridge construction of steel is typified in the Hell Gate bridge over the East river, and the Washington bridge at 181 street in New York city. This form of construction has been widely used for both railroad and highway traffic. Other outstanding steel arch bridges are at Niagara Falls, N.Y., Cleveland, O., Needles, Calif., Minneapolis, Minn., Oregon City, Ore., and over the Colorado river near Golfack, Ariz. A high steel arch bridge, the Kill Van Kull, planned to be opened in 1932 between Bayonne, N.J., and Pt. Richmond, Staten island, N.Y., calls for an outlay of \$16,000,000.

The cantilever bridge is more difficult to treat architecturally than any other type because the engineering requirements are so rigid that even such a broad matter as a pleasing silhouette is difficult to achieve. Consequently, the architectural treatment of cantilever bridges is generally confined to approaches and foundation piers. Among the more important bridges in this group are the St. Lawrence at Quebec, Ont., Canada, and the Carquinez strait, across the San Francisco bay, Calif. The Quebec bridge with a channel span of 1,800 ft. is the longest cantilever bridge in the world. Other notable structures of this type are at Pittsburgh, Pa., Memphis, Tenn., Thebes, Ill., Niagara Falls, N.Y., Poughkeepsie, N.Y. and Montreal, Canada.

The simple truss is somewhat more elastic for aesthetic modification. One of the largest of such bridges in the United States is the Castleton railroad bridge across the Hudson in the State of New York, having two main channel spans totalling 1,800 feet. Over the Ohio river, at Metropolis, Ill., a simple truss bridge has been constructed with a single span of 720 feet. Other such bridges are located in St. Louis, Mo., Sciotoville, O., Buffalo, N.Y. (International Peace Bridge); Louisville, Ky. and Cincinnati, O.

Steel suspension bridges offer considerable opportunity for architectural treatment because each has at least two sustaining piers to carry the cables and the catenary curve taken by any cable when loaded evenly throughout its length is in itself a very beautiful line. If the piers supporting the cables are of masonry the architect can produce a graceful and imposing mass in effective contrast to the web-like line of the cable and the balancing curve of the roadway. If the supporting piers are all of steel, as is more often the case, the proportions of the steel supports can be carefully studied to fit grace of line and mass to engineering requirements. There are examples where the steel piers supporting the cables have been encased with masonry, somewhat like the skeleton frame of a sky-scraper, giving the masonry the appearance of a solid pier, as is the case with the great Hudson river suspension bridge now under construction. The Delaware river bridge over the Delaware river between Philadelphia, Pa., and Camden, N.J., with a main channel span of 1,750 ft., is an example of co-ordination between engineering and architecture. Another imposing suspended bridge is the Bear Mountain over the Hudson above New York city, with a span of 1,632 feet. The Williamsburg,

Manhattan and Brooklyn bridges in New York city, and the Ohio at Cincinnati are suspended structures. The Ambassador bridge joining Detroit with Sandwich, has a central span of 1,850 feet.

**BRIDGES: CONSTRUCTION.** The design and construction of a bridge involve a combination of science and practical knowledge to an extent not required in perhaps any other engineering work. Lavish outlay of money and great accumulations of material in the structure itself will not necessarily result in a

FIG. 1.—ONE OF THE SEVEN INDEPENDENT SPANS, EACH 416 FT. LONG, THAT MAKE UP HAWKESBURY BRIDGE, N.S.W., AUSTRALIA

strong and enduring bridge; the latter may, on the contrary, weaken it by the imposition of material in the wrong place so that the added weight does positive harm. This is particularly the case in bridges of large span, which cannot be built without a thorough knowledge of the materials that can be used in their construction.

#### TYPES OF BRIDGE

All bridges belong to two main groups, fixed or opening, and can be divided into the following types:—

| Fixed            | Opening       |
|------------------|---------------|
| Independent Span | Swing         |
| Continuous Span  | Bascule       |
| Arch             | Rolling       |
| Cantilever       | Vertical Lift |
| Suspension       | Transporter   |

There are also bridges supported upon floating pontoons instead of upon solid piers, but essentially they belong either to the fixed or opening group.

#### FIXED BRIDGES

**An independent span**, one that reaches from abutment to abutment, or pier to pier, without projecting beyond the supports. The stresses set up by its own weight, or dead load, and by the loads that pass over it, or moving or live load, can be calculated with great accuracy, and it is therefore known as a determinate structure. Bridges of this type usually consist of main girders placed below or above the platform they support, the girders having top and bottom booms, either curved or straight, connected together by web systems of many different types each with its own advantages and name. The girders are proportioned so that the depth is usually from one-eighth to one-twelfth of the

FIG. 2.—CONTINUOUS SPANS OF BRITANNIA BRIDGE, MENAI STRAITS, WALES. THE TWO CENTRAL SPANS ARE EACH 460 FT. LONG AND THE SMALLER PAIR, 230 FEET

span, the greater the depth the stiffer being the girder. The top boom is in compression while the bottom is in tension, the web members being in tension or compression according to their position. The limiting span for this type is about 800 feet. Fig. 1 illustrates Hawkesbury bridge in Australia with seven spans of 416ft. each.

**Continuous Spans**, those that reach over more than one opening, usually three. They have the advantage of being lighter and

### CANTILEVER BRIDGES IN EUROPE AND AMERICA

1. View of the Quebec bridge, crossing the St. Lawrence river nine miles west of Quebec. This bridge, having a channel span of 1,800 feet between pier centres, was completed on September 20, 1917, when the 640-foot suspended span was hung on the cantilevers and bolted into its final position. Two serious accidents which occurred in 1907 and 1916, during the process of construction, necessitated changes in the original design and delayed the completion of the bridge
2. The Poughkeepsie railway bridge, crossing the Hudson river at Poughkeepsie, New York. This reverse cantilever bridge, 2,260 feet long and 200 feet above the water, carries the trains of the Central New England railroad across the Hudson. It was completed in 1889 and rebuilt in 1904
3. The Queensboro cantilever bridge, which crosses the East river between Second avenue, Manhattan, and Long Island City, with sustaining towers on Blackwell's Island
4. The Forth bridge, crossing the Forth river, in Scotland, at a point where the channel is divided by the island of Inchgarvie. The two main spans of this cantilever bridge, completed in 1889, are 1,710 feet each, the length is 5,330 feet, and the extreme height of the towers above high water is 361 feet
5. The Outerbridge, crossing from Tottenville, Staten Island, to Perth Amboy, New Jersey, opened for traffic on June 29, 1928. The main span, centre to centre of piers, is 750 feet; the total length, plaza to plaza, is 10,140 feet, and the over-all width of the bridge is 55 feet

of being deflected less than independent spans, but the stresses are more difficult to determine and great change of stress takes place in them if the supporting piers subside by even a small amount. While largely discarded in Europe, this type of bridge is being increasingly developed in America. However, in addition to the problems of stress, this type has the disadvantage of alterations in length, due to temperature, which are difficult to arrange for, as

FIG. 3.—ARCH SPAN AT SYDNEY, AUSTRALIA. 1,650 FT. LONG. THIS, WHEN COMPLETED, WILL BE THE LARGEST ARCH SPAN IN THE WORLD

they represent the total variations of several openings. Britannia bridge (fig. 2), with two spans of 460ft., and two of 230ft., is continuous over all three piers, and the expansion and contraction to be dealt with at each end amounts to a total of 4 inches.

**The Arch**, probably the most graceful type of all, can be constructed in many different materials. An arch usually consists of part of a solid ring or of a series of arched ribs, backed up by solid or open spandrels until a level line is reached upon which the floor or deck is constructed. The arched ring or ribs spring from sloping surfaces called skewbacks formed in the abutments and piers. The stresses in an arch are difficult to determine, and the calculations have to be based upon certain more or less arbitrary assumptions. With a view to making the structure conform with the calculations, especially in the case of large metal ribs, round pins are inserted at the skewbacks, and in some cases at the centre as well, to ensure that the stresses pass through these points. Arches are known according to the number of pins, as no-pinned, two-pinned or three-pinned, and in the latter case the stresses are quite determinate.

The usual proportion of rise of arch to span is about one-tenth, and the depth of the arch ring, or ribs, varies from about one-

FIG. 4.—CANTILEVER SPANS IN THE BRIDGE AT BUDAPEST. THE MAIN SPAN, 574 FT. LONG, IS MADE UP OF TWO CANTILEVERS, EACH OF 210 FT. AND A SUSPENDED SPAN OF 154 FEET

twenty-fifth of the span in the case of masonry structures, to about one-fortieth in a steel rib. In all arches the arch ring is in compression under the permanent or dead load, but when heavy moving or live loads pass over the bridge, reversals of stress may take place that may lead to the distortion and failure of the arch if these have not been allowed for in the design. Arches up to about 400ft. span have been constructed in masonry or reinforced concrete and, until recently, 600ft. has been considered the limit for mild steel, but with the advance in the knowledge of the theory of structures, Hell Gate bridge, New York, with a span of 1,017ft., has been successfully completed, and Sydney bridge, Australia (fig. 3) with a span of 1,650ft., is under construction. This bridge, when completed, will be the largest arch in the world. It has been designed as a two-pinned arch and will carry a roadway 57ft. wide, together with four railway tracks and two footpaths, and its total width will be 160 feet. The cost is estimated at £4,200,000.

In the United States increasing numbers of arch bridges, of concrete or reinforced concrete, have been constructed since the World War, especially in connection with the development of streets and highways. Noteworthy examples are the Hampden County Memorial bridge at Springfield, Mass.; the Cappelen Me-

morial bridge at Minneapolis, Minn.; the Arroyo Seco bridge at Pasadena, Calif.; the Ft. Snelling-Mendota bridge in Minnesota; and the Memorial bridge at Wilmington, Delaware.

**The Cantilever** type is often adopted when large spans have to be constructed, the limiting size being as high as about 3,000 feet. The principle is that of two projecting arms reaching towards each other, the gap between their ends being bridged by means of an independent, or suspended, span. The weight of all these is balanced by projecting arms reaching shorewards and anchored down. The stresses are quite determinate but, as in all large structures, the calculations are laborious and many secondary stresses have to be investigated. The effect of wind on large structures of this type is very serious and, in the Forth bridge, with spans of 1,710ft., the amount of steel provided to resist the stresses set up by this agency amounts to 47% of the total weight of the cantilevers. Fig. 4 shows the cantilever bridge at Budapest with a main span of 574ft. made up of two cantilevers of 210ft. and a suspended span of 154 feet.

**The Suspension**, a type which lends itself readily to the construction of the largest spans, the theoretical limit being in the neighbourhood of 7,000 feet. Camden bridge over the Delaware river has been constructed with a span of 1,750ft., and a bridge of double this span has been commenced over the Hudson river

FIG. 5.—MAIN SUSPENSION SPAN, 1,470 FT. LONG, IN MANHATTAN BRIDGE, NEW YORK. EIGHT RAILWAY TRACKS, A ROADWAY, AND TWO FOOTPATHS ARE CARRIED BY THIS BRIDGE

at New York. A suspension bridge consists of steel wire ropes or steel links of high tensile strength passing over lofty towers and anchored at each end. The platform for the roadway is suspended from the main ropes or chains by means of vertical ropes, and the change of form and swaying set up by moving loads is largely reduced by means of horizontal stiffening girders placed at road level. This type is not usually adopted for railway bridges on account of the changes of form that take place in spite of the stiffening girders. However, in large spans the inertia of the dead weight of the bridge is so great that this difficulty has been largely overcome, and both the completed large suspension bridges referred to above, together with others of older date, have railway tracks on them. Manhattan bridge, New York (fig. 5), constructed

FIG. 6.—SWING SPANS: RODAH BRIDGE, CAIRO. THIS SPAN GIVES TWO PASSAGES, EACH 65 FT. 6 IN. WIDE. THE CENTRAL SUPPORT TAKES UP VALUABLE WIDTH, 67 FT. 6 INCHES

1903-9, carries eight railway tracks, together with a roadway 35ft. wide and two footpaths.

#### OPENING BRIDGES

**The Swing Span** is probably the most usual type of opening bridge, the structure being pivoted so that it revolves in a horizontal circle. The arms on each side of the pivot may be of equal length, in which case they balance each other, but if of unequal length, the shorter is provided with weights or kentledge until a

balance is reached. In common with all opening bridges the motive power may either be human labour or some mechanical power exerted by hydraulic or electric machinery. To reduce the effort required, the weight of the span is usually carried by a number of radially set rollers running on a circular track, the function of the pivot being largely a centring one. The objection to this type of bridge is that the supporting pier, together with its protective works, occupies a large amount of space and if, as is often the case, it is located in the centre of a river, collisions with it are apt to take place, and in any case, valuable width is wasted. The

FIG. 7.—BASCULE SPANS (SCHERTZER FORM): QUEENSFERRY BRIDGE, CHESTER, ENGLAND

The waterway between the supports is 134 ft. wide. The supporting piers occupy little width in this form, those shown being each 10 ft. wide

Rodah bridge at Cairo (fig. 6), has a swing span giving two openings of 65ft. 6in. each, but it will be noticed from the drawing that as much as 67ft. 6in. is taken up by the central support and its protective staging.

**The Bascule**, a type consisting of one or two counter-weighted leaves working on horizontal pivots. The leaves rotate through about 90°, and the supporting piers being on each side of the waterway, a clear channel in the middle is provided for traffic. The weight of the leaves is of necessity concentrated on the pivots or trunnions, and this is a very serious matter in large spans. The difficulty has, to some extent, been got over by enlarging the pivots until they are virtually wheels, as in the Schertzer form, but large concentrations of loads seem to be unavoidable with this type of bridge. In the case of the new Schertzer opening bridge at Queensferry, Chester (fig. 7), the obstruction in the river has been reduced to two small piers, each 10ft. wide, the opening leaves being constructed somewhat narrower than the approach spans and rotating back on to them.

**The Rolling Type.**—Here the moving span is mounted upon wheels or rollers that allow it to be moved bodily away from the

FIG. 8.—ROLLING SPANS: NEWPORT DOCKS BRIDGE, ENGLAND

This bridge spans a lock 72 ft. wide, and is rolled into position by hydraulic power

opening at right angles to it, but in order that this may be accomplished, it must either be lifted vertically in order that it can roll back upon the approach, or the approach must be lowered. This is a somewhat complicated arrangement, and not many bridges of this type have been constructed. Fig. 8 shows one of the few constructed in Great Britain and situated at the Newport docks.

**The Vertical Lift Type.**—This has many advantages, and quite a number of bridges have been constructed on this principle in recent years in the United States. The weight of the bridge is taken by means of wire ropes that pass over pulleys at the top of tall towers and are then attached to counterweights. The height of the towers is such that when the bridge is raised vertically in the manner of a lift, there is sufficient clearance under the moving span for the river traffic to pass. As the weight of the bridge is balanced by the counterweights, the power required to open it is

only that necessary to overcome inertia, together with any friction between the guides fixed to the towers that also serve to keep the moving span in position. The bridge at Portsmouth, Me., U.S.A., (fig. 9), completed in 1924, has a lifting span of 300 feet, and the vertical clearance above high water when open is 150 feet.

**The Transporter Type**, more an aerial ferry than an opening bridge. It consists of an overhead bridge supported on lofty

FIG. 9.—VERTICAL LIFT SPAN, 300 FT. WIDE, PORTSMOUTH BRIDGE, MAINE, U.S.A. WHEN RAISED IT GIVES A CLEARANCE ABOVE WATER OF 150 FEET

towers, there being a moving cradle on its underside. A platform level with the banks of the opening is slung from the cradle, and on the cradle being set in motion the platform with its load of vehicles and passengers is ferried across the gap. This type has been adopted across wide busy rivers or harbours where the cost of a high level bridge with long approaches would be prohibitive, or where an opening span of a normal type would either be too

FIG. 10.—TRANSPORTER SPAN IN ROUEN BRIDGE, FRANCE

From the overhead span supported on high towers, a moving cradle, at level of banks of waterway, is slung and used to ferry vehicles and passengers

obstructive or too costly. Examples are to be seen at Newport, Widnes and Middlesbrough in Great Britain. M. Arnodin in France has devoted much attention to perfecting this kind of bridge, and fig. 10 represents one at Rouen erected by him.

### MATERIALS OF CONSTRUCTION

The chief materials are timber, bricks, stone, concrete, reinforced concrete, cast iron, wrought iron, mild steel and high tension steel.

**Timber** is now chiefly confined to temporary structures, except in development works in new countries. In order to increase its durability, it is often impregnated with creosote.

FIG. 11.—MAIDENHEAD BRICK BRIDGE, GREAT WESTERN RAILWAY, ENGLAND

The spans are each 18 ft. wide and the bridge is one of the largest brick bridges in the world. It was built in 1838 and is still used

**Bricks**, if carefully selected, have a life of hundreds of years. They can, of course, only be used in compression, and the safe working stress varies from about 8 tons per sq.ft., in the case of the softer varieties, to 12 tons per sq.ft. in the harder. The mortar used in setting them usually consists of one part of Portland cement to two parts of clean sand. The Great Western railway bridge at Maidenhead (fig. 11) was constructed in 1838 by Brunel

#### ARCHED BRIDGES IN THE UNITED STATES, GREAT BRITAIN AND CANADA

1. Study for the Kill van Kull bridge, a single span high arch steel bridge expected to be open to traffic in 1932, to cross the Kill van Kull from Bayonne, New Jersey, to Port Richmond, Staten Island
2. The Old Trails Highway, opened to traffic in 1916, single span arch across the Colorado river connecting California with Arizona, on the route of the Old Trails Highway near Topock, Arizona
3. Hell Gate bridge, single span steel-arch four-track railroad bridge across the East river, connecting the Pennsylvania Railroad and the New York, New Haven and Hartford Railroad, forming an all-rail line from New England, through New York City to the West and South; opened in 1917. From railing to railing it is 93 feet wide. The towers at each end rise 95 feet above the track level and their construction required 3 million cubic feet of masonry
4. The Newcastle-on-Tyne bridge, the largest steel arch in Great Britain, constructed in 1925-28 to carry the Great North Road across the Tyne at Newcastle. The total length of the bridge is 1254 feet; the carriage-way is 38 feet and each side-walk is 9 feet in width
5. The Royal Tweed road bridge, a huge ferro-concrete structure crossing the river Tweed at Berwick, Scotland, opened on May 16, 1928. To the left is the old stone bridge
6. Stony Creek bridge, over the gorge of that name, on the Selkirk range in British Columbia, erected in 1893, has a span of arch of 336 feet and is 300 feet high
7. The International (toll) Peace bridge, Buffalo, New York, connecting the United States with Canada at Fort Erie, Ontario. It was opened August 7, 1927

ARCHITECTURAL DRAWING FOR THE HUDSON RIVER BRIDGE

BY COURTESY OF THE PORT OF NEW YORK AUTHORITY

Drawing of the Hudson River bridge, designed by O. H. Ammann, Chief Engineer of Bridges, Port of New York Authority. Cass Gilbert, Architect. Ground broken Sept. 21, 1921, to be opened for traffic in 1932. The project involves a suspension bridge with a single span of 3,500 ft., which will cross the Hudson river from a point between 178th and 179th streets, Manhattan, to a point approximately opposite in Fort Lee, New Jersey

with two spans of 128ft. each, and is one of the largest brick bridges in existence. The arches settled when the centring was struck and doubts were expressed as to their stability, but they have stood the test of time well in spite of the fact that the weights of the trains passing over them have greatly increased since their completion.

**Stones.**—The stone used in bridge construction ought not only to be strong, but it should also be able to resist the disintegrating effects of heat, frost, rain and vibration. The safe working stress in compression is about 20 tons per sq.ft. for limestones and sandstones, increasing to about 30 tons per sq.ft. for granite and similar hard stones. For arched spans up to about 200ft., stone is the finest material that can be employed, and the resulting structure not only satisfies the eye but, if supported in solid foundations, it should endure for centuries with practically no upkeep. An interesting example is Waterloo bridge (fig. 12) which was completed in 1817 to the design of Sir John Rennie, who was also responsible for London bridge and old Southwark bridge. It has nine arches of 120ft. span. The piers and abutments were

FIG. 12.—STONE BRIDGES: WATERLOO BRIDGE, RENNIE'S MASTERPIECE, LONDON, COMPLETED IN 1817. IT CONSISTS OF 9 ARCHES EACH OF 120 FT. SPAN

founded on wooden platforms placed about flush with the bed of the river and supported on timber piles driven into the London clay.

**Concrete** is an artificial material consisting of broken stone or other hard aggregate, mixed with sand and Portland cement. These constituents are mixed dry in various proportions according to the strength required of the resulting material, and water is added. A chemical change takes place in the cement rendering it into a binding substance of very considerable strength. The usual working stress allowed in compression varies from 15 tons per sq.ft., for a concrete of one part Portland cement to two parts sand and four parts aggregate, to 5 tons per sq.ft. in a mixture containing these materials in the proportion one to four to ten.

**Cast Iron** was greatly used in the past on account of its high compressive strength and resistance to corrosion, but its weakness in tension led to its abandonment. In compression a working stress of 10 tons per sq.in. is quite allowable on short struts, but in tension this has to be reduced to  $2\frac{1}{2}$  tons per square inch. The Wearmouth bridge at Sunderland (fig. 13) was erected in 1796, and was one of the most daring structures ever erected in this

FIG. 13.—WEARMOUTH CAST IRON BRIDGE, SUNDERLAND, 1796

The span is 236 ft. wide, and the roadway is supported by 6 cast iron ribs material. It has a span of 236ft., and the roadway platform is supported by six cast iron ribs, each 5ft. deep but only 4in. wide. They were lightly braced together by cross-bracing and they safely carried the traffic. In 1859 Robert Stephenson inserted three wrought iron tubular ribs between each pair of cast iron ribs, and this composite structure is now being replaced by a steel arch of 375ft. span, but the original cast iron ribs are in perfect condition.

**Reinforced Concrete** is a composite material of construction in which the compressive stresses in the members are taken up by the concrete, while in the parts subjected to tension or shear, mild steel sections (usually round rods) are inserted to resist the tensile or shearing stresses to which the concrete itself can only offer a poor resistance. Being a composite material, whose strength depends upon the correct position of the steel reinforcement, it

FIG. 14.—REINFORCED CONCRETE BRIDGE, STEIN TEUFEN, SWITZERLAND

The span here is 259 ft. wide. Reinforced concrete permits graceful designs, but requires very careful supervision during construction

necessarily follows that, unless the work at the site is kept constantly under observation, errors creep in. The working stresses allowed are 16,000lb. per sq.in. in tension in the steel, and 600lb. per sq.in. in compression in the concrete of a proportion of one part of Portland cement to two parts of sand to four parts of aggregate, none of the latter being large enough to be retained by a mesh  $\frac{3}{4}$  in. square (fig. 14).

**Wrought Iron.**—The manufacture of this material as a reliable commercial product led to a great development in bridge construction about the middle of the last century, as it permitted the general adoption of types of bridges other than the arched.

FIG. 15.—MENAI WROUGHT IRON SUSPENSION BRIDGE, WALES, 1826

The main span is 580 ft. wide and the wrought iron link-chains are still perfectly sound

The usual working stresses are 5 tons per sq.in. in tension, 4 tons per sq.in. in compression in short struts, and 4 tons per sq.in. in shear. Wrought iron has a greater resistance to corrosion than mild steel, and there are numbers of bridges that were constructed in this material about 50 or 60 years ago that are still in good condition. The Menai suspension bridge (fig. 15) was constructed over 100 years ago (1819-26), and apart from corrosion at one particular spot, the wrought iron links, of which its main chains are composed, are still perfectly sound.

**Mild Steel** led to another considerable advance, especially in the size of the spans that could be adopted economically. The working stresses allowed are 8 tons per sq.in. in tension,  $6\frac{1}{2}$  tons per sq.in. in compression for short struts and 5 tons per sq.in. in shear. The working stresses in compression are usually based upon a formula that takes account of the column action in the member, a common form for compressive members with riveted

end connections being  $8(1 - 0.033\frac{l}{r})$  tons per sq.in.,  $l$  being the length of the member in inches, and  $r$  its radius of gyration, also in inches. The ultimate breaking strength of mild steel is usually specified as not to vary outside the limits of 28 to 32 tons per sq.in. with an extension of 20% in 8 inches. The chemical composition must be such that on analysis it must not show more than .06% of sulphur or of phosphorus.

The Quebec bridge (fig. 16), with a span of 1,800ft., is the largest cantilever bridge in existence and is an outstanding exam-

ple of a modern steel structure. It was opened in 1918 after the failure of one on the same site which collapsed in 1907 while being constructed. Misfortune dogged the second structure, as the suspended span fell as it was being erected, owing to faulty erection details, but the main structure was undamaged and a new suspended span was safely got into position. The river cantilevers and the suspended span were constructed of nickel steel.

**High Tension Steel** has been developed to meet the demand for still greater spans. The material itself is more expensive than mild steel, but the additional cost is largely counterbalanced by the saving in the amount of steel required. The increase in

FIG. 16.—QUEBEC STEEL BRIDGE, CANADA, LARGEST CANTILEVER BRIDGE IN THE WORLD

The main span is 1,800 ft. wide; the landward cantilevers are of mild steel while the river cantilevers and the suspended span are of nickel steel

strength beyond mild steel has been obtained either by increasing the proportion of carbon or by the introduction of nickel, chromium or other metals. In the former case, the working stress has been raised to 9 tons per sq.in. in tension with a corresponding increase in compression and shear. For alloy steels, such as nickel and silicon steels, the figure is 10.5 tons per square inch. As was mentioned, nickel steel was used in the suspended spans of Quebec bridge, while silicon steel was used in the stiffening trusses of the Camden bridge, 1,750ft. span, at Philadelphia, and the Bear mountain bridge, 1,632ft. span, over the Hudson. This material is also to be largely used in the Sydney bridge ribs of 1,650ft. span. The main members of the Hell Gate arch (fig. 17) at New York, span 1,017ft., were constructed of high carbon steel.

### BRIDGE DESIGN

**Loads and Forces.**—In designing a bridge the following loads and forces have to be taken into account:—dead load, live load, impact, deformation stresses, wind pressure, centrifugal effect, longitudinal forces, temperature effect and erection stresses. The most important of these, in the case of bridges of moderate span, are the dead and live loads and impact.

The *dead load* is the weight of the bridge itself, together with

FIG. 17.—HELL GATE ARCH, HIGH TENSION STEEL BRIDGE, NEW YORK  
Constructed of high carbon steel, the span is 1,017 ft. wide

any fixed loads it may have to carry. The *live load* is the weight of the traffic using the bridge. *Impact* is the additional effect set up by the live load due to its speed, and it is usually allowed for by multiplying the live load by a factor based upon the span. The *deformation stresses* are those induced by change of shape in the structure due to riveted and eccentric connections. The *wind pressure* is usually assumed as a moving load of 50lb. per sq.ft., acting on the exposed surface of the unloaded bridge. The leeward surface is also taken into account if it is distant more than twice the depth of the windward girder. With the bridge under live

load, the wind pressure is reduced to 30lb. per sq.ft., but the area is increased by the exposed surface of the moving load. This reduction is based upon the fact that the moving load could not reach the bridge at higher wind pressures than 30lb. per sq.ft. as vehicles are overturned at pressures in excess of that amount. The *centrifugal effect* is only taken into account in the case of a railway bridge situated on a curve. The *longitudinal forces* are those due to the tractive effect of the live load and the braking effect resulting from the application of the brakes. *Temperature effect* is that due to variations of temperature, the coefficient of expansion of mild steel being taken at  $\frac{1}{4}$  inch for every hundred feet for a variation of  $40^{\circ}$  F above or below the normal, which is the amount usually taken in temperate climates. *Erection stresses* are those set up temporarily during erection and for which an excess of 33% over the permanent stresses may be allowed.

FIG. 18

**Straining Actions in a Beam.**—When a horizontal beam *AB* (fig. 18) is supported at its two ends *A* and *B* and loaded with a weight *W* at any point *C*, the following actions are set up:—(1) A bending action, known as bending moment, whose intensity at any point may be represented graphically as a triangle with its apex at the load, and mathematically, as the reaction at *A* or *B* multiplied by the distance to the point selected; i.e., BM at *C*=

$$W \times \frac{CB}{AB} \times AC; \text{ and BM at any point } D = W \times \frac{CB}{AB} \times AD. \text{—(2) A}$$

shearing action, whose intensity at any point may be represented graphically by two parallelograms meeting under the load, and, mathematically, as equal to the reactions at *A*, for the left-hand parallelogram, and to the reaction at *B* for the right-hand; i.e.,

$$\text{Shear } A \text{ to } C = W \times \frac{CB}{AB} \text{ and shear } C \text{ to } B = W \times \frac{AC}{AB}. \text{—The maxi-}$$

mum bending moment occurs when *W* is in the centre of the span *L*, i.e., when  $AC = CB = \frac{AB}{2}$ , and its intensity becomes

$$\frac{W}{2} \times \frac{C}{2} = \frac{WL}{4}; \text{ while the maxi-}$$

mum shear occurs when *W* is just over *A* or *B*, when its intensity becomes *W*.

If the load *W* is spread uniformly over the span (fig. 19), the bending moment may be represented graphically by a parabola and, mathematically, by the reaction at *A* multiplied by the distance to any point selected, less the intervening loads, multiplied by their distance from the point selected, i.e.,

FIG. 19

$$BM \text{ at } C = \frac{W}{2} \times AC - \left( W \times \frac{AC}{AB} \times \frac{AC}{2} \right).$$

If *w* represents the weight per unit of length, then  $W = wL$ , and if *x* be the distance *AC*, then the foregoing may be written:—

$$\frac{wL}{2} \times x - wL \times \frac{x}{L} \times \frac{x}{2} = \frac{wx}{2} (L - x).$$

The shear may be represented by two triangles meeting at the middle of the span, where its intensity is zero, and, mathematically, as equal to the reaction at either end, less the portion of the load between the point selected and the reaction, i.e., shear at

$$C = \frac{W}{2} - \frac{W \times AC}{AB} = \frac{wL}{2} - \frac{wL \times x}{L} = w \left( \frac{L}{2} - x \right).$$

The maximum bending moment occurs at the centre where  $x = \frac{L}{2}$ .

and its value is, therefore  $\frac{wL^2}{8}$  or  $\frac{WL}{8}$ ; while the maximum shear is at the ends, and has the value  $\frac{wL}{2}$  or  $\frac{W}{2}$ .

**Straining Actions in a Cantilever.**—In the case of a cantilever (fig. 20), with a load  $W$  at the extreme end, the bending moment may be represented by a triangle whose maximum depth is at the support, where obviously the intensity is  $WL$ , and the value at any other point is  $W$  multiplied by the distance from  $W$  to the point. The shear can be represented by a parallelogram whose depth is equal to  $W$ . If  $W$  be spread uniformly over the span (fig. 21), then the bending moment diagram becomes a parabola, the intensity at the support being  $\frac{WL}{2}$  or  $\frac{wL^2}{2}$  if the

FIG. 20

load per unit of length is  $w$ . The value at any other point is the product of the loads to the right of the point multiplied by half the distance between the point selected and the end of the cantilever. The shear gradually increases from zero, at the end, to a maximum of  $W$ , at the support, and so can be represented by a triangle whose depth at the support is equal to  $W$  or  $wL$ .

**Calculation of Stresses in a Girder.**—The bending moment caused by a load, or system of loads, is resisted by the amount of material in the beam, but this resistance varies, not only with the amount and strength of the material, but with its shape or disposition. The moment of resistance is the summation of the products obtained by multiplying the strength of each small component of the cross section by the distance of its centre of gravity from the central or neutral axis. In the case of a rectangular cross section (fig. 22) width  $b$ , depth  $d$ , the moment of

FIG. 22

resistance equals  $f \frac{bd^3}{12}$ , where  $f$  is the strength of the material for unit sectional area. If  $b$  were reduced to  $\frac{b}{2}$  while  $d$  was increased to  $2d$ , the area of the cross section would be the same, but the moment of resistance would have increased fourfold to  $f \frac{bd^3}{3}$ . It is evident from this that the greater the depth, or the more the material can be kept away from the neutral axis, the stronger the beam for a given amount of material.

This is effected in practice by the use of a thin web with flanges top and bottom (fig. 23). The web is of so little value in comparison with the flanges that it is usually neglected in considering the moment of resistance which is then arrived at by multiplying the area of one flange by the vertical distance between their centre of gravity. If  $a$ =area of one flange,  $d$ =distance between centres of gravity, and  $f$  be the safe working stress of the material, the moment of resistance= $fad$ . This can be equated to the bending moment, as they must be equal for safety, so that  $BM$ =moment of resistance= $fad$ . To ascertain the sectional area of the flanges, all that is therefore necessary is to divide the bending moment by the depth of the girder, multiplied by the safe working stress:— $a = \frac{BM}{df}$ . The most economical depth varies from about one-tenth to one-fifteenth of the span. When the span exceeds about

FIG. 23

50ft., a solid web usually becomes uneconomical, and it can be replaced by a system of vertical posts and inclined ties or struts. These members can be arranged in various ways, each type having its own name, such as Pratt, Warren, Linville, etc.

The stress in each member of such a lattice girder can be obtained either graphically by means of a stress diagram, or analytically. The graphical method is as follows:—make an outline diagram of the girder, or truss, as it is often called (fig. 24), using a definite scale, and letter each compartment according to Bow's

FIG. 24

notation. Set out the loads below each other using any convenient scale (fig. 25). Calculate the end reactions and mark them off on the scale of loads. Fig. 25 shows a Pratt truss so treated. The truss is in equilibrium and consists of a series of triangles, and, by a proposition in statics, the forces acting on these triangles can be represented by a closed polygon, each side of which is parallel to one force and represents the force in magnitude and direction. From point  $P$ , draw  $PA$  parallel to member  $PA$  on the truss. From  $O$  draw  $OA$  parallel to member  $OA$ . These two lines intersect at  $A$ , and the sides of the triangle  $OPA$  represent the forces (to scale) acting in members  $PO$ ,  $OA$  and  $AP$  in magnitude and direction. The character of the force, whether compression

FIG. 25

or tension, can also be ascertained by noting the sequence of the reading of the forces. Taking the sequence at point  $P$ ,  $PA$  reads away from  $P$ ; put an arrow on the truss diagram indicating that direction.  $OA$  reads towards  $P$ ; indicate this with an arrow. Repeat this later at each point and it will be found that arrows  $><$  indicate tension in the member and arrows  $<>$  indicate compression. Having solved triangle  $OPA$ , draw from point  $A$  a line  $AB$  parallel to member  $AB$ , and from  $Q$  a line  $QB$  parallel to member  $QB$ . These lines  $AB$  and  $QB$  intersect at  $B$ , and the sides of the polygon  $PABQ$  represent the forces acting in members  $PA$ ,  $AB$ ,  $BQ$  and load  $QP$  in magnitude and direction. Proceed thus until all the members of the truss have been dealt with.

FIG. 26

Analytically, the stresses may be found as follows. Assume for simplicity uniform loadings at each equal panel point (fig. 26),

then:  $R = 3W + \frac{W}{2} = 3\frac{1}{2}W$ . The shearing or vertical forces must obviously be taken by the vertical posts in the truss.

$$\text{Stress in } FG = R - (W + W + W) = 3\frac{1}{2}W - 3W = \frac{W}{2}$$

$$\text{stress in } DE = R - (W + W) = 3\frac{1}{2}W - 2W = 1\frac{1}{2}W$$

stress in  $BC = W$ , as it is merely a hanger transmitting load  $W$  to the point  $B$ .

The stress in the diagonals is due to their transmitting the vertical shearing forces in a diagonal direction from the bottom to the top boom; their values will, therefore, be the vertical shear multiplied by  $\frac{\text{length of diagonal}}{\text{length of vertical post}} = \text{shear} \times \sec\theta$ , if  $\theta$  be the angle of the diagonal members to the vertical.

$$\text{Stress in } FI = \frac{W}{2} \times \sec\theta,$$

$$\text{stress in } DG = 1\frac{1}{2}W \times \sec\theta,$$

$$\text{stress in } BE = 2\frac{1}{2}W \times \sec\theta,$$

$$\text{stress in } AB = 3\frac{1}{2}W \times \sec\theta.$$

The stress in the bottom flange  $AC$  and  $CE = \text{stress in } AB \times \sin\theta = 3\frac{1}{2}W \sec\theta \cdot \sin\theta = 3\frac{1}{2}W \tan\theta$ .

The stress in the bottom flange  $EG = \text{stress in } AE + \text{stress in } BE \times \sin\theta = 3\frac{1}{2}W \tan\theta + 2\frac{1}{2}W \tan\theta = 6W \tan\theta$ .

The stress in the bottom flange  $GI = \text{stress in } EG + \text{stress in } DG \times \sin\theta = 6W \tan\theta + 1\frac{1}{2}W \tan\theta = 7\frac{1}{2}W \tan\theta$ .

The stress in top flange  $BD = \text{stress in } AB \times \sin\theta + \text{stress in } BE \times \sin\theta = 3\frac{1}{2}W \tan\theta + 2\frac{1}{2}W \tan\theta = 6W \tan\theta$ .

The stress in top flange  $DF = \text{stress in } BD + \text{stress in } DG \times \sin\theta = 6W \tan\theta + 1\frac{1}{2}W \tan\theta = 7\frac{1}{2}W \tan\theta$ . The stress in top flange  $FH = \text{stress in } DF + \text{stress in } FI \times \sin\theta = 7\frac{1}{2}W \tan\theta + \frac{1}{2}W \tan\theta = 8W \tan\theta$ .

The stresses may also be obtained by Ritter's method of sections when a section of a girder can be taken cutting only three bars. In fig. 27,  $BQ$  cuts three bars. Assume that the forces in these bars are  $x$ ,  $y$  and  $z$ . To the left of the section there are three external forces, reaction  $R$  and loads  $W_1$  and  $W_2$ . Produce the two forces  $x$  and  $z$  until they intersect at point  $G$ . Drop a perpendicular from point  $G$  to the extension of force  $y$  at a distance  $d$ . Taking moments about  $G$  and, since the truss is in equilibrium, equating them to zero:—

$$\begin{aligned} R \times AG - WCG - WEG - yd &= 0. \\ y &= \frac{3\frac{1}{2}W \times 3EG - 2WEG - WEG}{DE} = 7\frac{1}{2}W \tan\theta. \end{aligned}$$

To find the value of  $z$ , take moments round point  $D$  where forces  $y$  and  $x$  meet:—

$$\begin{aligned} R \times AE - WCE - zd &= 0 \\ z &= \frac{3\frac{1}{2}W \times 2CE - WCE}{DE} = 6W \tan\theta. \end{aligned}$$

To find the value of  $x$ , take moments about  $A$  after dropping a perpendicular of length  $l$  from  $A$  to extension of force  $x$ :—

$$x = \frac{yd - WAC - 2WAC}{l} = \frac{7\frac{1}{2}W \tan\theta DE - 3WAC}{3AC \cos\theta} = 1\frac{1}{2}W \sec\theta.$$

Generally, if  $S$  is the stress in any bar and  $L$  the perpendicular distance from the join of the other two bars cut by the section, and  $M$  is the moment of the forces on one side of that join, then  $SL = M$ .

**Influence Lines** are curves showing, for one component part of a beam or truss, the shearing force, bending moment, stress, deflection or similar function for all positions of a moving load.

Referring again to the simple beam, the bending moment diagram for a load  $W$  at  $C$  indicates that the amount of bending at  $D$  is represented by the ordinate  $dd'$  (fig. 28). Similarly, if the load is moved to  $E$ , the corresponding bending moment indi-

cates the amount of bending at  $D$  to be  $dd''$ . For a number of positions of the load, the amount of bending at  $D$  may be plotted as ordinates on a graph whose abscissae are the corresponding positions of the load. The resulting curve will be the influence line for the case in question and as indicated on the figure. This

FIG. 28

particular influence line further indicates that for all positions of the load there is induced a bending moment of the same type; and for a uniform load, the maximum bending moment at  $D$  would be attained by loading the whole span. More generally, where a moving load may induce either a positive or negative effect on a member, the influence

line gives a ready means of showing where load should be applied in order that the maximum possible effect may be attained.

**Calculation of Stresses in a Continuous Girder.**—When girders are carried continuously over more than two supports, or where the girders, instead of merely resting, are more or less rigidly built into the supports, the reactions of the supports cannot be established by the usual elementary methods. This is due to the fact that the continuity, or building-in fixity, alters the simple distribution of the reactions. The *theorem of three moments* supplies an equation enabling the bending moments over the supports to be calculated, and hence the reactions may be determined. Fig. 29 indicates the spans of a continuous girder.

The general equation for these two spans is:—

$$M_p \times l_p + 2M_q(l_p + l_q) + M_r \times l_q + \frac{6A_p \times x_p}{l_p} + \frac{6A_q \times x_r}{l_q} + 6EI \left( \frac{S_p}{l_p} + \frac{S_r}{l_q} \right) = 0$$

$M_p, M_q, M_r$  are the bending moments at  $P, Q$  and  $R$  respectively.  $A_p, A_q$  are the areas of the bending moment diagrams on spans  $l_p$  and  $l_q$  respectively, due to the loads on these spans, the spans for this purpose being considered as separate independent spans.  $x_p$  is the distance of the centre of gravity of  $A_p$  from support  $P$ .  $x_r$  is the distance of the centre of gravity of  $A_q$  from support  $R$ .  $E$  = modulus of elasticity of material of girder.  $I$  = moment of inertia of girder.  $S_p, S_r$  are the distances which support  $Q$ , falls or rises below or above supports  $P$  and  $R$  respectively.

This equation is applied to consecutive pairs of spans from end to end of the girder, and thus furnishes the necessary equations to solve the bending moments over the supports. Of necessity the section and modulus of elasticity of the girder and the relative deflection of the supports must be known beforehand. Accordingly, the design of continuous girders usually necessitates the adoption of trial and error methods before suitable sections can be chosen. Usually, the moment of inertia is assumed to be constant throughout the girder, otherwise the general equation requires considerable modification in detail.

FIG. 30

**Calculation of Stresses in a Metal Arch.**—The stresses in a metal arch are the same as those in the curved top member of a braced girder in which the bottom tie has been replaced by unyielding abutments, and the web system has been omitted (fig. 30). If the arch is loaded uni-

formly, the stress at the crown, or the horizontal thrust at the springing, is  $H = \frac{WL}{8R}$ , where  $L$  is the span and  $R$  is the height or rise. The thrust in the arch at any other point is proportional to the secant of the angle  $\alpha$  that a tangent line to the curve at that point makes with the horizontal, and its value is  $H \sec \alpha$ .

These values would be absolutely correct in the case of an arch of parabolic outline uniformly loaded, as its centre line would then conform to the outline of the bending moment diagram, and the thrusts would all be absolutely central. In actual practice an arch, even if parabolic in shape, is not subjected to a uniform dead load, on account of the varying dimensions and weight of the spandril filling necessary to secure a horizontal platform, and the arch itself is not rigid but elastic, and changes shape under the moving loads. The foregoing values for the thrust can, therefore, only be looked upon as approximate and the stresses are, in reality, indeterminate, except in the case of the three-pinned arch where pins or hinges have been inserted both at the springings and crown. Many different mathematical studies have been made, based upon assumptions as to the elastic properties of metal arches, or upon the theorem of least work. They yield approximate solutions that, by repeated trial and error, give results within a close margin of each other, and permit the safe design and construction of arches of very large span, the most impressive example of which is the Sydney bridge now under construction, with a span of 1,650 feet.

**Calculations of Stresses in a Masonry Arch.**—As in the case of the steel arch, the masonry arch may be considered as the top chord of a bow-string girder, taking compression and also shear stress, the thrust from the skewbacks taking the place of the bottom chord tension member. For any loading, the bending moment diagram, as drawn for the equivalent beam span, gives the ideal shape that can be adopted for the arch. Since, however, the loading on a bridge varies, the best design for the arch is that which will most nearly follow the lines of thrust for all cases, and at the same time give as small bending action as possible. Many shapes have been adopted for arches, *e.g.*, semi-circular, segmental, elliptical basket-handle, gothic.

The most generally used materials are brick, stone and concrete. None of these materials is adapted to withstand tensile stress. The normal rule which automatically provides a factor of safety is that the thrust should be confined to the middle third of the rib section. This implies absence of tension, together with the fact that the maximum stress never exceeds twice the average. A further implication is that the average stress is usually low and, consequently, the dead weight of the arch increases rapidly with the span, thus severely limiting this type of construction for large spans. The great majority of masonry arches are hingeless partly due to the fact that until recently the theory of the arch has not been fully understood. The accurate determination of stress where there are no hinges is extremely difficult, owing to the nature of the materials. For instance, when mortar joints set, the consequent general settlement, though minute, may entirely alter the stress distribution. The introduction of reinforced concrete into arch construction, with the consequent permission of tensile stress, has opened the field considerably for larger spans. The largest reinforced arch which has been constructed, namely the Pont Adolphe, Luxembourg, has a span of 278ft., while the bridge at Berwick, commenced in 1925, includes a reinforced concrete span of 361ft. 6 inches.

**Manufacture.**—In the case of masonry bridges, complete detail drawings are prepared of every stone to be dressed, and these are sent to the quarries from which the material is to be obtained. Each stone is cut exactly to size and numbered so that when sent to the site it fits accurately into place, allowance having been made for the joints and beds which are usually  $\frac{1}{4}$ in. thick. For metal bridges, detailed drawings are made of each member, and lists of all the different materials required sent to the rolling mills in the case of mild steel, or to the foundry in the case of cast iron or other castings. While this material is being prepared, the work is drawn out full size on the floor of a building termed the template loft. Here templates of thin wood or sheet iron are cut to the right shape, and holes are drilled through them where every rivet or bolt is to go. When the material arrives at the bridge yard the templates are laid upon it, every hole marked out with steel punches, and the required shape and length outlined.

After that, it is passed to the sawing, shaping, planing and drilling benches. It is then assembled into units and riveted

up. The units or members are assembled together temporarily to form complete girders to make certain that they fit each other properly, and after being painted with identification marks, they are dismantled and forwarded to the site.

**Piers and Abutments.**—The supports upon which a bridge rests are termed abutments in the case of those at the ends, and piers in the case of those occupying intermediate positions. They may take the form of timber or concrete piles driven hard into the ground, or screw piles of cast iron may be used in soft soils. All these are suitable for light structures, but the most usual form of support consists of a mass of concrete or masonry carried down to firm ground. The necessary excavation is done inside a timber or steel cofferdam, or box, to exclude any water that may be present and to hold up the ground, the sides of the cofferdam being formed by rows of piles which are either drawn or cut off at a convenient level at the conclusion of the work.

Another common form of support is obtained by sinking cylindrical or rectangular caissons, and loading them with temporary weights or with the masonry of the pier or abutment itself. The ground inside the area of the caisson is excavated by digging, compressed air being employed if necessary to keep the water out. The weighted caisson keeps following the excavation down, and, when a satisfactory stratum is reached, the whole or remainder of the caisson is filled with concrete. If any doubt exists as to whether the foundations are satisfactory, they are test-loaded by means of weights, temporarily placed upon them, equal to the full load that they may ever have to carry, and the subsidence is noted. In normal circumstances, the cost of the substructure and the cost of the superstructure should be approximately equal, and this serves as a useful check on the efficiency of the design.

### ERECTION

Generally speaking, there are four ways of erecting a bridge, *viz.*, by means of temporary staging, by cantilevering out, by rolling out or by floating out. The erection of a bridge very often involves some of the most difficult problems in connection with the project.

**Temporary Staging** is the most usual method of erection. The staging is arranged so that its upper surface conforms with the outline of the under surface of the bridge to be erected, and it usually consists of timber piles, each 12in. square in cross

FIG. 31.—TEMPORARY STAGING, WASHINGTON BRIDGE, NEW YORK  
The staging consists of timber piles driven into the ground and braced by horizontal and diagonal members, the whole conforming to the shape of the bridge to be built. In this bridge, the staging utilized  $1\frac{1}{2}$  million cu. ft. of timber

section, having a sharp point shod with a cast iron shoe, and driven sufficiently far into the ground to be secure against any undermining forces, *e.g.*, the scouring effect of the flow of any water that may come against it. The piles are spaced at such a distance apart that they are sufficient to take the loads that will come upon them from the dead weight of the bridge as it is being erected, together with the necessary cranes, etc., described as "plant."

After the piles have been driven, they are braced together by horizontal and diagonal members to ensure that the structure will not sway or go out of shape. The top surface is decked over to form a supporting and working platform. After the permanent work has been completed and is carrying its own weight, the staging is removed, the piles being either drawn or cut off flush with the bed of the river. Some stagings have to be of a very elaborate character, *e.g.*, those used for the Washington bridge in

New York (fig. 31), where  $1\frac{1}{2}$  million cu.ft. of timber were used in piles and bracings. No settlement or displacement occurred.

**Cantilevering out** is adopted in cases where it is not possible to employ a staging, or where its use would be extremely expensive, for instance, where a wide and deep or a busy river has to be crossed. In such a case the difficulties of erection may often control the whole design of the bridge, ruling out what

FIG. 32.—CANTILEVERING OUT, WEAR BRIDGE, SUNDERLAND, ENGLAND

otherwise would be a cheaper and more convenient type, and the bridge may have to be erected by cantilevering out, *i.e.*, each member is bolted at one end, the other end projecting. The free end is then made secure by another member being added to tie it back to the main structure. This process is repeated until by working from both sides of the opening to be spanned, the members meet in the middle. If there is a central tower the process can be reversed, the work proceeding from the centre of the river or gap shorewards, the only precaution to observe being that the members must be erected so that they balance each other, otherwise the whole structure might overturn.

The cantilever type of bridge, by virtue of its shape and design, readily lends itself to this method of erection, which, however, can be applied to other types as well though temporary members have to be added. These usually consist of a mast placed over each abutment with ties from the top down to the shore, where an anchorage can be obtained, and to the projecting ends of the work. Independent and continuous girders and arches have all been erected in this way, though in many cases they have to be specially stiffened to resist the stresses temporarily set up during erection as they differ from the final stresses. In large structures, the changes of form, due to the stresses and to the temperature, have also to be taken into account and allowed for. One disadvantage of this method of erection is that it is difficult to supervise the men engaged in the work, and readjustments are difficult to make once a member is in position. Fig. 32 shows the roadway and railway bridge, over the River Wear at Sunderland, under erection. The work was of a heavy character, the stresses

FIG. 33.—ROLLING OUT, GRAND FEY VIADUCT, FRIBOURG, SWITZERLAND  
This bridge was first assembled and then rolled into its final position

in the temporary back stays amounting to 1,200 tons, and special hydraulic jacks, capable of exerting a force of 1,600 tons, were used for adjusting them so that the two halves of the structure were in perfect alignment and level when they met.

**Rolling Out** is a modification of cantilevering out and can only be applied to independent and continuous spans. The bridge is constructed in some convenient position. Roller wheels are then placed under the completed work or unit, and the whole

pushed or pulled forward into its final position. A false nose is often fitted to the front end, so that a support on the opposite side, or on intermediate piers, can be obtained as soon as possible, and the rear end is loaded with heavy material to prevent the front end toppling over into the gap over which it is being projected. Temporary stresses and change of form have to be carefully studied as in the cantilever method. In favourable circumstances this is a cheap method of erection, and has the advantage that the actual assembling of the material can be kept under close observation. The viaduct at Grand Fey, Fribourg (fig. 33) was erected in this way.

**Floating Out.**—The structure is first constructed on a staging or on some convenient site, and then transferred to floating pontoons or barges placed alongside. At a period of slack water, the whole combination is towed to the site of the bridge and adjusted in line with the piers or abutments, but with a small vertical clearance. Water is admitted to the pontoons and they sink until the structure takes its bearings

FIG. 34.—FLOATING OUT, on the masonry, when the pontoons are withdrawn or the falling tide releases them. This method cannot well be adopted where there is a fast running stream or very short periods of slack water as any error in manipulating the pontoons might lead to the total collapse of the bridge. The operation was repeated many times without a hitch during the erection of the Tay bridge (fig. 34). The actual floating out of the 245ft. spans, weighing 514 tons each, and getting them into position occupied only four hours for each span.

on the masonry, when the pontoons are withdrawn or the falling tide releases them. This method cannot well be adopted where there is a fast running stream or very short periods of slack water as any error in manipulating the pontoons might lead to the total collapse of the bridge. The operation was repeated many times without a hitch during the erection of the Tay bridge (fig. 34). The actual floating out of the 245ft. spans, weighing 514 tons each, and getting them into position occupied only four hours for each span.

#### DESCRIPTIONS OF SOME IMPORTANT BRIDGES

London bridge was designed by Sir John Rennie and built during the period 1824-31. Its arches, of which there are five, vary in size from 130ft., in the case of the side arch, to 152ft. for the centre. It was originally 54ft. wide, but was widened (1902-04) to 65ft. by carrying the footpaths on granite corbels. The bridge is of granite, and its total cost was approximately £1,500,000, of which £692,000 was for the purchase of land.

The Forth bridge has a total length of 5,330ft., made up of two cantilever spans of 1,710ft. each, two shore arms of 680ft. each, the remaining distance being occupied by steel towers. It cost £3,200,000, and is probably the most impressive bridge in existence. It was designed by Sir Benjamin Baker, and was constructed during the period 1882-89. The clear headway above high water is 150ft., and the towers are 361ft. high. The cantilevers project 680ft. and support suspended spans of 350ft. in length.

The Camden bridge, Philadelphia, built over the Delaware, 1921-26, at completion the largest suspension bridge in the world, has a span of 1,750ft. It is 125ft. in width, and designed to carry a central roadway 57ft. wide with four railway tracks and two footpaths in addition. It is supported by two main cables, 30in. in diameter, there being 18,666 wires laid parallel to each other in each main cable. The clearance above high water is 135ft. The bridge cost, with its approaches but without land, about \$25,000,000, the total cost being nearly \$35,000,000. It was designed by Ralph Modjeski and erected by a board of engineers under his direction.

The Hudson river bridge, New York city, was begun in 1927 and was at that date by far the largest span bridge ever attempted, having a span of 3,500ft. and a width of about 140ft. It is designed to carry a roadway 95ft. wide with four railway tracks and two footpaths in addition. The clearance above high water is to be 200ft. The towers will be 635ft. high, and are to be of steel with an outer shell of masonry. The final total cost is estimated at about \$60,000,000.

The Tower bridge, London, was built 1886-94 at a total cost of £830,000. It has an opening span of 200ft. clear between the two main towers. The side spans are suspended from braced chains, whose pull is taken up by heavy masonry anchorages at the shores and by a steel tie concealed in the horizontal girder that unites the towers at a height of 141ft. above high water. The towers are of steel, faced with granite and Portland stone.

The opening span consists of two leaves or bascules, pivoted at the faces of the towers and counterweighted at their shorter end; they are operated by hydraulic power and take about one and a half minutes to open fully. The bridge was designed by Sir John Wolfe Barry and his partners.

The Newcastle-on-Tyne bridge was begun in 1925 and was opened in the autumn of 1928; it is the largest arched bridge in Great Britain. It has a span of 531ft. and a width of 64ft. between parapets with a headway for navigation of 84ft. The main arch springs from the quay levels on each side of the river, and is supported by concrete abutments carried down to the sandstone

rock. The abutment towers have been designed to contain lifts for giving access from the bridge roadway to the quays. The approximate cost was £750,000 excluding land and property, which brought the total amount up to about £1,200,000—little short of half as much again as the Tower Bridge.

Alexander III. bridge, Paris, built during the period 1896–1900, is remarkable on account of the very flat rise given to its arch in order to provide easy gradients from the quays on each side of the river. The rise of 20ft. 7in. is only one-seventeenth of the span of 353ft. The ribs are of cast steel, and they have pins both at the abutments and at the centre.

BRIDGET, SAINT (453-523), one of the patron saints of Ireland, was born at Fochart, in county Louth, her father being a prince of Ulster, and her mother a bondmaid. Bridget and her

mother were sold to a wizard, who brought up the little girl, and on being converted by her to Christianity, gave her back her freedom. Thereupon she returned to her father's house, where she gave so many of his goods to the poor that on her refusal to marry he tried to sell her to the king of Ulster. The latter was so struck by her piety that he freed her from parental control, and she founded a church and monastery at Kildare. She died on Feb. 1, which is celebrated as her feast day. Under the name of St. Bride she became a favourite saint in England, and numerous churches were also dedicated to her in Scotland.

See the five lives given in the Bollandist *Acta Sanctorum*, Feb. 1, i. 99, 119, 950. Cf. Whitley-Stokes, *Three Middle-Irish Homilies on the Lives of Saint Patrick, Brigit and Columba* (Calcutta, 1874); Colgan, *Acta SS. Hiberniae*; D. O'Hanlon, *Lives of Irish Saints*, vol. ii.; Knowles, *Life of St. Brigid* (1907); further bibliography in Chevalier, *Répertoire des sources hist. Bio.-Bibl.* (1905).

**BRIDGET, BIRGITTA, OF SWEDEN, SAINT** (c. 1302–1373), the most famous saint of the northern kingdoms, was the daughter of Birger Persson, governor and provincial judge of Uppland. In 1316 she married Ulf Gudmarson, lord of Nericia, and of her eight children, one became St. Catherine of Sweden. About 1342 she went with her husband on pilgrimage to St. James of Compostella, but shortly after their return, Ulf died in the Cistercian monastery of Alvastra and Bridget, already famous for her saintly and charitable life, devoted herself wholly to religion. The spiritual impressions which she had experienced in her childhood now became more frequent, and her records of them, translated into Latin by Matthias, canon of Linköping, and by her confessor, Peter, prior of Alvastra, obtained a great vogue during the middle ages. She founded the order of St. Saviour, or Bridgittines (*q.v.*), of which the principal house, at Vadstena, was richly endowed by King Magnus II. and his queen. About 1350 she went to Rome, partly to obtain from the pope the authorization of the new order, partly in pursuance of her desire to elevate the moral tone of the age. It was not till 1370 that Urban V. confirmed the rule of her order; but meanwhile Bridget had made herself universally beloved in Rome. Save for occasional pilgrimages, including one to Jerusalem in 1373, she remained in Rome till her death on July 23, 1373. She was canonized in 1391 by Boniface IX.

**BIBLIOGRAPHY.**—The Revelations were published several times, the best edition being that of G. E. Klemming (1857–84) (Eng. trans. 1873). Cf. the Bollandist *Acta Sanctorum*, Oct. 8, the *Vita Sanctae Brigittae*, ed. by C. Annerstedt in *Scriptores rerum Suedicarum mediæ ævi*, iii. 185–244 (Uppsala, 1871); de Flavigny, *Sainte Brigitte de Suède, sa vie, ses révélations et son oeuvre* (1892); Binder: *Die hl. Birgitta von Schweden u. ihr Klosterorden* (Munich, 1891). For full bibliography see Chevalier, *Répertoire des sources hist.* Bio.-Bibl.

**BRIDGETON**, a city in southern New Jersey, United States, 38m. S. of Philadelphia, at the head of navigation on the Cohansey river; the county seat of Cumberland county. It is served by the Central railroad of New Jersey and the Pennsylvania railroad. The population in 1920 was 14,323, and in 1930 was 15,699 by Federal census. It is the social and commercial centre of a rich agricultural region, and has well-established industries, the most important of which are the manufacture of glass bottles, jars and plate-glass; the canning of fruits and vegetables; iron works, and machine shops. The output of the 57 establishments in the city in 1925 was valued at \$12,898,723. Considerable local capital is invested in the oyster industry at Bivalve, in the southern part of the county. Bridgeton still has its "Liberty Bell," which rang from the court house in 1776; and there are numerous survivals of 18th century architecture, notably the Broad Street Presbyterian church, built in 1792 from the proceeds of a lottery authorized by the legislature for the purpose. City park and lakes contain 1,000 ac. of picturesque natural beauty.

The first rude bridge across the Cohansey, which gave the town its name, was built in 1716. In 1749 the hamlet was chosen by popular election for the county seat, and in 1754 a town was laid out. A mail route to Philadelphia, with daily deliveries, was established in 1802. At this time the principal industry was cutting cordwood for the Philadelphia market. A woollen mill was established in 1811, a nail and iron works in 1815, the first glass works in 1830, and the first canning factory in 1860. Bridgeton was designated a port of entry, but it never had much foreign commerce. The city was incorporated in 1864. In 1907 a new charter was adopted, providing for a modified commission form of government.

**BRIDGEWATER, FRANCIS EGERTON**, 3RD DUKE OF (1736–1803), the originator of British inland navigation, younger son of the first duke, was born on May 21, 1736. Scroop, first duke of Bridgewater (1681–1745), was the son of the third earl of Bridgewater, and was created a duke in 1720; he was the great-grandson of John Egerton, first earl of Bridgewater (d. 1649; cr. 1617), whose name is associated with the production of Milton's *Comus*; and the latter was the son of Sir Thomas Egerton (1540–1617), Queen Elizabeth's lord keeper and James I.'s lord chancellor, who was created baron of Ellesmere in 1603, and in 1616 Viscount Brackley (*q.v.*).

Francis Egerton succeeded to the dukedom at the age of 12, on the death of his brother, the second duke. Shortly after attaining his majority he became engaged to the beautiful duchess of Hamilton, but her refusal to give up the acquaintance of her sister, Lady Coventry, led to the breaking off of the match. Thereupon the duke broke up his London establishment, and retiring to his estate at Worsley, devoted himself to the making of canals. The navigable canal from Worsley to Manchester, which he projected for the transport of the coal obtained on his estates, was (with the exception of the Sankey canal) the first great undertaking of the kind executed in Great Britain in modern times. The construction of this work, with its famous aqueduct across the Irwell, was carried out by James Brindley, the celebrated engineer. In 1762 he obtained parliamentary powers to provide an improved waterway between Liverpool and Manchester by means of a canal, which was completed in 1772. The difficulties were still more formidable than those of the Worsley canal, involving, as they did, the carrying of the canal over Sale Moor Moss.

He died unmarried on March 8, 1803, when the ducal title became extinct, but the earldom of Bridgewater passed to a cousin, John William Egerton, who became seventh earl. By his will he devised his canals and estates on trust, under which his nephew, the marquess of Stafford (afterwards first duke of Sutherland), became the first beneficiary, and next his son, Francis Leveson Gower (afterwards first earl of Ellesmere) and his issue. The trust did not expire till Oct. 19, 1903, when the whole property passed under the undivided control of the earl of Ellesmere. The canals, however, had in 1872 been transferred to the Bridgewater Navigation Company by whom they were sold in 1887 to the Manchester Ship Canal Company.

**BRIDGEWATER, FRANCIS HENRY EGERTON**, 8TH EARL OF (1756–1829), was educated at Eton and Christ Church, Oxford, and became fellow of All Souls in 1780, and F.R.S. in 1781. He succeeded to the earldom in 1823, and spent the latter part of his life in Paris. He was a fair scholar and a zealous naturalist and antiquarian. At his death the earldom became extinct. He bequeathed to the British Museum the valuable Egerton mss. dealing with the literature of France and Italy, and also £12,000. He also left £8,000 to the president of the Royal Society for a work on apologetics by a writer or writers to be selected. The work was divided among eight authors, whose treatises, known as the Bridgewater treatises, appeared between 1833 and 1840.

The Bridgewater treatises were published as follows:—1. *The Adaptation of External Nature to the Moral and Intellectual Condition of Man*, by Thomas Chalmers, D.D. 2. *The Adaptation of External Nature to the Physical Condition of Man*, by John Kidd, M.D. 3. *Astronomy and General Physics considered with reference to Natural Theology*, by William Whewell, D.D. 4. *The Hand, its Mechanism and Vital Endowments as evincing Design*, by Sir Charles Bell. 5. *Animal and Vegetable Physiology considered with reference to Natural Theology*, by Peter Mark Roget. 6. *Geology and Mineralogy considered with reference to Natural Theology*, by William Buckland, D.D. 7. *The Habits and Instincts of Animals with reference to Natural Theology*, by William Kirby. 8. *Chemistry, Meteorology, and the Function of Digestion, considered with reference to Natural Theology*, by William Prout, M.D. The works are of unequal merit; several of them took a high rank in apologetic literature. They were reprinted in Bohn's Scientific Library.

**BRIDGEWATER**, a town of Plymouth county (Mass.), U.S.A., 27m. south of Boston. It is served by the New York, New Haven and Hartford railroad. The population in 1930 (Federal census) was 9,055. The manufactures include shoes, nails, lumber, tubes and brick. A State normal school (established 1840) is pleasantly situated near the centre of the town. In 1656 the part of Duxbury called New Plantation was established as the town of Bridgewater. North, West and East Bridgewater were separately established in 1821, 1822 and 1823.

**BRIDGING, MILITARY.** In the course of most military operations it is necessary to cross rivers at places where no bridges exist or where they have been demolished by the enemy. It is the duty of the engineers of an army to provide the means for such crossings. For small detachments ferrying with boats or rafts is resorted to, but for forces of any size accompanied by artillery and transport bridges must be built. Floating bridges are the

most rapidly built and have consequently been most frequently employed; they are built either with material obtained locally or with special "pontoon" equipment accompanying the army on wagons. Many other types of construction have been employed such as trestle bridges in which the roadway is supported by a series of timber trestles, cribwork bridges in which the supports consist of timber cribs usually filled with stone, pile bridges, suspension bridges and steel or wooden girder bridges. So long as transport and guns were drawn by animals the weight of vehicles was limited and consequently the strength required of military bridges remained approximately constant until the beginning of the 20th century. With the introduction of motor vehicles and tanks, however, weights increased enormously and all bridging standards had to be reconsidered.

#### HISTORY AND DEVELOPMENT

From time immemorial floating bridges of vessels bearing a roadway of beams and planks have been employed for the passage of rivers and arms of the sea. Xerxes crossed the Hellespont on a double bridge, one line supported on 360, the other on 314 vessels anchored head and stern with their keels in the direction of the current. Darius threw similar bridges across the Bosphorus and the Danube in his war against the Scythians, and the Ten Thousand employed a bridge of boats to cross the river Tigris in their retreat from Persia. Floating bridges have been repeatedly constructed over rivers in Europe and Asia, not merely temporarily for the passage of an army, but permanently for the requirements of the country; and to this day many of the great rivers in India are crossed by floating bridges which are for the most part supported on boats such as are employed for ordinary traffic on the river. Alexander the Great is said to have carried his army over the Oxus by means of rafts made of the hide tents of his soldiers stuffed with straw when he found that all the river boats had been burnt. Cyrus crossed the Euphrates on stuffed skins. In the 4th century the emperor Julian crossed the Tigris, Euphrates and other rivers by bridges of boats made of skins stretched over osier frames. In more recent times bridges have been supported on floating piers made of barrels lashed together. During the World War light footbridges for the assaulting infantry were frequently made supported by floats composed of cork or empty petrol tins held together in light crates. Bivouac sheets stuffed with straw were also used as in the days of Cyrus and Alexander.

**Principles of Pontoon Equipments.**—All the devices mentioned above are still occasionally used but they depend upon materials to be found on the spot and these are rarely available in sufficient quantities and furthermore take time to collect. For these reasons pontoon equipments were introduced. Such equipments consist of sets of stores designed for the construction of floating bridges; packed on wagons they accompany an army and are available for use wherever required. There are three essential parts, floating supports called "pontoons" anchored at intervals in the stream with their keels in the direction of the current; beams called "baulks" or "road-bearers" spanning the intervals between pontoons and supporting the roadway; and finally the roadway itself composed of planks technically known as "chesses." To understand the history of their development the qualities desirable in these parts must first be considered.

The pontoons must have sufficient buoyancy to support the loads which are to use the bridge; within limits the power of support can be increased by placing them closer together, but in rapid currents the water-way must not be unduly obstructed or the bridge will be washed away. They must be light enough to be man-handled and to be loaded upon wagons. They must be strong enough to withstand rough usage and should be easily repairable in the field. These requirements are contradictory and the history of pontoon design is a history of compromise. The most usual form is that of a flat-bottomed boat either with or without a deck; decked it can with safety be more deeply loaded, but its interior is inaccessible and it is less convenient for use as a boat.

The road-bearers must be strong enough to support the roadway, and must also be as light as possible for transport. Evidently, the greater the intervals between the pontoons the greater

the strength required. They may rest either on a central saddle placed longitudinally on each pontoon vertically above the keel—"saddle loading"—or simply upon the gunnels of the pontoons—"gunnel loading." Saddle loading makes for great simplicity in constructing the bridge, each set of road-bearers spanning from the centre of one pontoon to the next with claws or pins on their ends which engage in the saddles. Gunnel loading does not require such strong road-bearers since the spans are shorter; it also adds stiffness to the bridge, but the fastenings are more complicated. Until the advent of mechanical transport wooden road-bearers about 5 in. by 4 in. in section and 15 to 20 ft. long were usually employed.

The chesses must be as light as is consistent with strength. In the days of horse-drawn traffic 1½ in. was the usual thickness; for heavy traffic a second layer was laid on top of the first.

**History of Pontoon Equipment.**—Alexander the Great occasionally carried with his army vessels divided into portions which were put together on reaching the banks of a river, as in crossing the Hydaspes. The practice of carrying about skins to be inflated when troops had to cross a river was adopted by the Greeks, the Romans and the Mongols and indeed still exists in the East. In the wars of the 17th century pontoons are found as regular components of the trains of armies, the Germans using a leather, the Dutch a tin and the French a copper "skin" over stout timber frames. In the middle of the 18th century the Russians introduced a collapsible pontoon consisting of a tarpaulin skin stretched on a wooden frame. For transport the frame was dismantled and the tarpaulin rolled up; this type they retained for a hundred years.

During the 19th century a great number of designs were introduced only a few of which can be mentioned here. No army had more experience of pontooning than the French; during the wars of the Revolution and the Empire they constructed pontoon bridges over most of the principal rivers of Europe. They experimented with many types ranging from large wooden boats weighing about 2 tons to small copper ones weighing 7 cwt.; the heavy wooden type, the Gribeauval, was discarded in 1805 as it could not keep up with the movements of the armies; in 1853 they adopted a flat-bottomed open wooden boat 31 ft. long and weighing 1,450 lb., which appears to have been very successful and was extensively used by the Northern States during the American Civil War.

During the Peninsular War the English employed open pontoons, but the experience gained during that war induced them to introduce the closed form. Gen. Colleton devised a buoy pontoon, cylindrical with conical ends and made of wooden staves like a

FIG. 1.—KAPOK ASSAULT BRIDGE, SHOWING THE BUOYANT CUSHIONS FILLED WITH KAPOK, A LIGHT COTTON-LIKE SUBSTANCE OBTAINED FROM TREES NATIVE TO JAVA AND THE INDIAN ARCHIPELAGO. THESE CUSHIONS REMAIN AFLOAT EVEN WHEN REPEATEDLY PUNCTURED BY RIFLE FIRE

cask. Then Gen. Sir Charles Pasley introduced demi-pontoons, like decked canoes with pointed bows and square sterns, a pair, attached stern-wise, forming a single "pier" of support for the roadway; they were constructed of light timber frames covered with sheet copper and were decked with wood; each demi-pontoon was divided into watertight compartments and provided with means for pumping out water; for transport a pair of demi-pontoons and the superstructure for one bay of bridge were loaded on a single wagon. The Pasley was superseded by the Blanshard pontoon, a tin-coated cylinder with hemispherical ends for which

great mobility was claimed, two pontoons and two bays of superstructure being carried on one wagon. The Blanshard pontoon was long used in the British army, but was ultimately discarded, and British engineers reverted to the open pontoon to which the engineers of all the Continental armies had meanwhile constantly adhered. Capt. Fowke, R.E., invented a folding open boat made of waterproof canvas attached to sliding ribs, so that for transport it could be collapsed like the bellows of an accordion and for use could be extended by a pair of stretchers. This was fol-

FIG. 2.—KAPOK ASSAULT BRIDGE IN POSITION. IT IS RAPIDLY LAUNCHED, AND PROVIDES PASSAGE FOR INFANTRY

lowed by a pontoon designed by Col. Blood, R.E., an open boat with decked ends and sides partly decked where the rowlocks were fixed. The sides and bottom were of thin yellow pine with canvas secured to both surfaces with india-rubber solution, and coated outside with marine glue. The central interval between the pontoons in a bridge was 15ft.; five baulks were ordinarily used, nine for the passage of siege artillery and the heaviest loads; saddle loading was employed. One pontoon with one bay of superstructure were loaded on a wagon. This equipment was later modified by the introduction of an undecked bipartite pontoon designed in 1889 by Lieut. Clauson, R.E. As its name implies this pontoon was in two sections, a bow section and a stern section, coupled together with easily manipulated couplings of phosphor bronze. For light bridges the sections could be used independently; for heavy bridges three sections could be coupled together end to end. Except for minor modifications this equipment was retained in the British service until 1924. During the World War it was much used in Mesopotamia and during the early and final stages in France; it was found unsuitable in the rapid current of the Piave on the Italian front.

Historically the most important equipment is that introduced in the Austrian army by Col. Birago in 1841; it was either adopted or copied by many other armies. The Birago pontoon was a flat-bottomed open boat constructed in sections two or more of which could be coupled together end to end to form piers of the buoyancy required. This idea had first been proposed by Col. Pompei Floriani about the middle of the 17th century but had not previously been fully developed; as already mentioned it was subsequently adopted in British equipments. The Birago pontoons were in the first instance made of wood, later they were made entirely in iron and later still in steel. One reason given for the change was that metal pontoons were more easily repaired in the field than wooden ones; this argument, however, would not generally be accepted. Saddle loading was adopted, the saddle being arranged to slew in the pontoon so that a bridge could be built diagonally across a river, the pontoons still pointing in the direction of the current; great importance was attached to this feature at the time but it was not subsequently found to be practical.

An interesting equipment was introduced into the American army in 1846. The pontoons were made entirely of india-rubber and each consisted of three parallel pointed cylinders 20ft. long joined together side by side by an india-rubber web. When the pontoon was required for use these cylinders were inflated through nozzles with a pair of bellows; for transport the entire pontoon was folded up and packed in a box. After considerable experience during the American Civil War the engineers of the Northern States much preferred the French equipment.

#### Methods of Bridge Building with Pontoon Equipment.—

There are four recognized methods of building pontoon bridges;

the choice depends partly upon the actual equipment in use and more upon the site of the bridge and nature of the river. (a) "Forming up." In this method pontoons are added successively to the "head" or far end of the bridge and the roadway added on top of them; this is perhaps the simplest method. (b) "Booming out." Pontoons are added successively at the "Tail" or shore end and the whole bridge pushed out, this saves carrying all the stores for the roadway to the far end of the bridge. (c) "By rafts." Complete sections of the bridge are built in convenient positions by the near bank, floated into position and joined together; this method will often be quicker than (a) or (b). (d) "Swinging Bridge." The entire bridge is built alongside the near bank, that is, at right angles to its final position; when complete it is allowed to swing round with the current on its near end as a pivot, anchors are dropped in their appropriate positions as it swings and the entire bridge is checked by the anchor cables as it reaches its correct alignment. On a suitable site this method is extremely rapid, but in fast streams the operation is risky and the bridge often is lost or severely damaged.

**Trestle Bridges.**—It is not always feasible to construct a floating bridge, pontoons may not be available, the water may be too shallow or the gap may be entirely dry. In such cases timber trestles have frequently been used to replace pontoons as supports for the road-bearers. Such trestles consist essentially of a horizontal bottom piece or "ground sill," two or more legs which are vertical or slightly inclined inwards at the top, and a horizontal top piece or "transom" on which the ends of the road-bearers rest as they would on the saddle of a pontoon; the whole is stiffened up by diagonal braces. The size of the timber used varies with the nature of the bridge, ranging from light army signal poles used for the trestles of infantry assault bridges during the World War to timber baulks 12in. square or even larger used for railway bridges during the American Civil War and the Boer War and for heavy road bridges during the World War. In the case of light and very temporary trestles the members may be fastened together by means of wire or even rope lashings, but where any strength or permanency are required they must be properly fitted and spiked or dogged together. High railway viaducts have been built by placing two or even three heavy trestles on top of each other to form each pier and bracing the whole together. Trestles are usually constructed on shore, carried into position and up-ended; in the case of the heaviest trestles derricks have to be employed. After losing his pontoons in the retreat from Moscow Napoleon crossed the Beresina on a trestle bridge. The trestles were placed by hand by men working waist deep in the icy water. Most pontoon equipments have included specially designed trestles for use where the water close to the shore is not deep enough to float a pontoon.

**Cribwork.**—Timber cribs have been used instead of trestles for railway and heavy road bridges when timber was plentiful and the height required small. They were much used during the Boer War in the repair of demolished railway bridges, railway sleepers being employed in their construction. Timber crib construction is very convenient since no skilled labour is required but cribs are wasteful of material. When placed in water they are usually spiked together and filled with stone. During the World War 3ft. cubes made of light steel angles riveted together were kept as an article of store and extensively used for building up piers of moderate height for heavy road bridges. An instance occurred in 1918 in the crossing of the Selle where, under the nose of the enemy holding the opposite bank, a crib causeway for tanks, built of railway sleepers, bolted together and sunk in the bed of the river was constructed during the nights immediately preceding the attack and kept concealed from view and from aerial photography by being completed just below water-level.

**Pile Bridges.**—Trestles or Cribwork are often not feasible in rapid currents owing to the scour and if pontoon equipment is not available pile driving has to be resorted to, but it is a slow method. In 1809, before the battle of Wagram, Napoleon's engineers under Gen. Bertrand constructed a pile bridge 800yd. long across the Danube at Vienna in 20 days; upstream, piles were driven to form a "boom" to protect the bridge from floating bodies sent down by the enemy.

**Girder Bridges.**—Unlike the types described above girder bridges can span clear gaps of roof. or more without any intermediate support. They were first extensively used during the World War in France. Standard patterns were manufactured in large quantities, parts were as far as possible interchangeable and bridges could be built of any multiple of the fixed panel length up to a maximum which depended on the loads which were to use them. The Hopkins type of girder bridge and the Inglis were the most important types; both were "through" bridges, the roadway being carried between two Warren girders. The Hopkins followed the lines of ordinary civil practice except that bolts were substituted for rivets to facilitate erection in the field. In the Inglis the principal members were tubular and were connected into special cast junction pieces by pins and locking rings. The method usually employed was to build the bridge on dry land in rear of the gap and then launch it over rollers by means of derricks and winches on the far bank.

#### DEVELOPMENTS SINCE THE WORLD WAR

**Assault Bridging.**—Forcing the passage of a river in the face of the enemy is a difficult operation under modern conditions. It will usually be necessary to pass the assaulting infantry over as rapidly as possible under cover of darkness and without making any preparations which would put the enemy on his guard. The use of improvised floating assault bridges during the World War has been referred to above. A special equipment for this purpose has since been introduced into the British service; it is known as the kapok assault bridge and is shown in figs. 1 and 2. This bridge consists of canvas floats stuffed with kapok, each bearing, strapped to it, a transom plate or saddle with a metal coupling to which are affixed the timber duckboards which form the bridge from float to float. At each end of the floats are handles so that the bridge, after being assembled at a convenient spot near the river, can be lifted bodily by two men for each float and carried forward for launching.

The operation of launching and pushing the bridge across the river can be effected in a few seconds, and as soon as it has been secured on the far bank the assaulting infantry can commence to cross. The articulation of the saddle joint allows sufficient play for the bridge to be carried and launched over rough ground whilst providing sufficient lateral rigidity to steer its head across the stream, even against cross-wind and current. The buoyancy

FIG. 3.—THE CONSUTA MEDIUM BRIDGE, A COMBINATION OF TRESTLE AND PONTOON BRIDGES

It serves for the passage of medium weight lorries, artillery, etc. behind advancing troops

of the floats is ample and the bridge is stable in the water. The virtue of the kapok float lies in its lightness and in the fact that it is little affected by rifle fire; even when repeatedly punctured it absorbs water very slowly. For the formation of a bridge to take pack transport three kapok assault bridges are placed side by side and planked over to form a roadway.

**Pontoon Equipments.**—Prior to 1914 the majority of military transport was still horse-drawn and vehicles weighed about 2 tons. The weight of field guns and howitzers was of the same order and heavier artillery was an exception for which it was not usually necessary to provide. The horse-drawn wagon has now

been replaced by the motor lorry weighing four times as much. Medium and heavy artillery are common and tanks weighing 12 tons or more must be passed across rivers with the minimum of delay. It has therefore been necessary to redesign pontoon equipments. The pattern adopted in the British service is shown in fig. 3. The pontoons are flat-bottomed boats with scow bows and are completely decked in, they are 21ft. long, 5ft. 6in. wide and 2ft. 9in. deep and weigh about 1,400 lb. They are built with a skin of two or three ply consuta wood on a mahogany framework and are designed so that two pontoons can be coupled stern to stern. The road-bearers are nickel chrome steel joists and are fitted at their ends with steel pins to engage in slots in the saddles which rest centrally on the pontoons. The chesses are 3in. thick and are held in place by wheel guides or "ribands" racked down by chains with a screw attachment. Fig. 3 shows the three forms in which the pontoon bridge may be made up; as a light bridge to carry field artillery and horsed transport, the pontoons being used singly with five steel road-bearers from saddle to saddle; as a medium bridge to carry medium artillery and lorries in which two pontoons are coupled stern to stern and seven road-bearers are used in each bay; as a heavy bridge to carry heavy artillery and track vehicles up to the 18 ton tank in weight, the piers of which are formed of four pontoons coupled in pairs and carrying an extra central saddle on which 11 road-bearers are placed to carry the roadway. In all forms each bay of bridge spans 21 feet. A steel trestle is provided as part of the equipment. It consists of two mild steel legs with pitch pine mud shoes, a nickel chrome steel transom and two jacks for raising or lowering the transom. The legs are drilled with holes along the centre of the web into which the pins of the transom engage so that the transom and, with it, the roadway can be raised or lowered by means of the jacks as occasion requires. When used in conjunction with a heavy bridge as shown in fig. 2, a double trestle pier is formed, but with a medium bridge a single trestle suffices to form a pier.

The French have adopted an undecked pontoon made of galvanized steel sheet on a steel framework; it is 33ft. long, 6ft. 6in. wide and 3ft. 3in. deep, weighs 2,420 lb. and is designed for gunnel loading. Experiments have been carried out with two systems of construction. In the first ordinary wooden road-bearers are used and lashed down to the pontoons; in the second an ingenious arrangement of articulating steel girders is added outside the roadway on each side to distribute the load between pontoons; the road-bearers in this case are of steel.

It will be seen that there is still wide divergence of opinion as to the best design for a pontoon equipment; on the whole it may be said that the metal pontoon is, in spite of its weight, gaining ground at the expense of the wooden one; that the boat-shaped pontoon has asserted its superiority over all other designs; and that decked pontoons are in the minority. Opinion on saddle versus gunnel loading is divided. Experiments with aluminium alloy pontoons have been undertaken in several countries, but nowhere have the practical difficulties yet been overcome.

**Girder Bridges.**—Steel girders are required for semi-permanent bridges on the lines of communication since pontoon equipment requires too much attention to be satisfactory for this purpose and will in any case be required to move forward with the army. It will be realized from the description given of them above that the Hopkins and the Inglis bridges required considerable time and skilled labour to erect. These objections have been largely overcome in the Martel box girder bridge (fig. 6 of the plate) since introduced into the British service. This is designed to enable all spans up to about roof. to be bridged in the simplest manner and also to secure that the bridge so built will be strong enough to carry either light, medium or heavy loads. The bridge is of the deck type and the chesses lie flat on the top of the box girders. The girders are skeleton steel boxes made up in sections, each 8ft. long. The sections are joined together by plain pin joints; no nuts or bolts are required. There are thus only two essential parts, viz., the box girders and the chesses.

Three types of bridge can be built by using two, three or four box girders under the chesses. In fact the gap is to all intents and purposes spanned by using skeleton steel road-bearers which can

be made up to any desired length in 8ft. sections. To obtain a wider bridge it is merely necessary to add more box girders and use longer chesses, or a double row of chesses. The decking is held in position by angle steel kerbs fixed down by hook bolts, and the handrail consists of posts which fit into the sockets in the centre of each 8ft. length of kerb and piping. The handrail pipes are also used as carrying bars for carrying sections of the girders. The girders will usually be fitted with horn beams at each end, a construction which enables them to be lowered on to masonry abutments, or on to a timber bankseat so that the level of the roadway may be kept down and a ramp-up approach avoided; but where head-room under the bridge is required or the approach level is suitable, these are not necessary. The girders may be launched by means of a derrick on the far bank or a cantilever method may be adopted if the bridge is a heavy one with three or four girders. In this case each girder is used in turn as a counter-weight for the next, the last girder being rolled across on deck planks laid on those already in position and then jacked down.

The construction of approach roads to a heavy bridge is often a work of greater magnitude than the construction of the bridge itself as they must be sufficiently permanent to carry the heavy strain of mechanical transport. Thus, whilst the assault bridges are intentionally thrown well away from the main lines of traffic and the lighter forms of pontoon bridge can be used wherever a reasonable cross country approach track can be made, the heavy bridges are confined closely to the route of the main roads.

**Probable Effect of Mechanical Warfare.**—Mechanical warfare is still in its infancy and the direction of its future development is uncertain. The effect on military bridging is therefore a matter of speculation. One of the chief assets of a mechanical force of tanks, armoured cars, etc., is its speed and power of movement over favourable ground independently of roads. Obviously it will frequently use this mobility to go round obstacles instead of spending time constructing bridges. Unless, however, it is provided with some means of rapidly crossing streams of moderate width much of the value of its mobility will be lost.

See Official army manuals on bridging (English, French, American, etc.), which are the best source of information. *The Work of the Royal Engineers in the European War 1914-1919, Bridging*, Institution of Royal Engineers, Chatham (1921), contains interesting photographs. (R. D. D.)

**BRIDGITTINES**, an order of Augustinian canonesses founded by St. Bridget of Sweden (q.v.) c. 1350, and approved by Urban V. in 1370. It spread widely in Sweden and Norway and in Northern Europe, and played a remarkable part in promoting culture and literature in Scandinavia; to this is to be attributed the fact that the head house at Vastein, by Lake Vetter, was not suppressed till 1595. In England, the famous Bridgittine convent of Syon at Isleworth, Middlesex, was founded and royally endowed by Henry V. in 1415, and was among the few religious houses restored in Mary's reign. On Elizabeth's accession the community migrated to the Low Countries, and finally (1594) settled in Lisbon. Here they remained, always recruiting their numbers from England, till 1861, when they returned. Syon House is now established at Chudleigh in Devon; and there are a few Bridgittine convents on the Continent.

See A. Hamilton in *Dublin Review*, 1888, "The Nuns of Syon"; Max Heimbucher, *Orden u. Kongregationen* (1907), ii. § 83; Herzog-Hauck, *Realencyklopädie* (ed. 3), art. "Birgitta." (E. C. B.)

**BRIDGMAN, FREDERICK ARTHUR** (1847- ), American artist, was born at Tuskegee, Ala., on Nov. 10, 1847. He began as a draughtsman in New York for the American Bank Note Company in 1864-65, and studied art in the same years at the Brooklyn Art school and at the National Academy of Design; but he went to Paris in 1866 and became a pupil of J. L. Gérôme. Paris then became his headquarters. A trip to Egypt in 1873-74 resulted in pictures of the East that attracted immediate attention, and his large and important composition, "The Funeral Procession of a Mummy on the Nile," in the Paris Salon (1877), bought by James Gordon Bennett, brought him the cross of the Legion of Honour. Other paintings by him were "An American Circus in Normandy," "Procession of the Bull

Apis" (now in the Corcoran Art Gallery, Washington), and a "Rumanian Lady" (in the Temple collection, Philadelphia).

He is an officer of the Légion d'honneur, and of the order of St. Michael of Bavaria. He was made a member of the National Academy in 1881. He is the author of *Winters in Algeria* and of *Anarchy in Art*. He has also composed orchestral music.

**BRIDGMAN, LAURA DEWEY** (1829-1889), American blind deaf-mute, was born on Dec. 21, 1829, at Hanover (N.H.), U.S.A. When two years old she had an attack of scarlet fever which permanently destroyed her sight and hearing. Through an article published by Dr. Mussey, head of the medical department of Dartmouth college, her case was brought to the attention of Dr. S. G. Howe, head of the Perkins institution for the blind at Boston. In Oct. 1837 Laura entered the school. Dr. Howe at once set himself to teach her the alphabet by touch. He first pasted on several common articles, such as keys, spoons, knives, little paper labels with the names of the articles printed in raised letters. As soon as she had learned all the names in this fashion she was taught the individual letters, and gradually learned the alphabet and the ten digits. In Jan. 1842 Charles Dickens visited the institution, and afterwards wrote enthusiastically in *American Notes* of Dr. Howe's success with Laura. In 1843, funds were obtained for devoting a special teacher to her, and first Miss Smith, then Miss Wight, and then Miss Paddock were appointed; Laura by this time was learning geography and elementary astronomy. In 1887 her jubilee was celebrated at the institution. In 1889 she was taken ill and died on May 24. She was buried at Hanover.

See Maud Howe and Florence Howe Hall, *Laura Bridgman* (1903), which contains a bibliography; Mary S. Lamson, *Life and Education of Laura Dewey Bridgman* (1878).

**BRIDGNORTH**, municipal borough, Shropshire, England, situated on a high, red sandstone rock bounded on the east by the River Severn. Pop. (1931) 5,151. The approach from all sides involves steep ascents or descents. The early history of Bridgnorth is connected with Aethelfleda, lady of the Mercians, who raised a mound there in 912 as part of her offensive policy against the Danes. William I. granted the manor to Earl Roger of Shrewsbury, whose son built a castle on the sandstone rock in 1101. The castle was finally destroyed by the parliamentary forces in the Civil War, with the exception of part of the keep. Early charters were confirmed by several later kings, and the town was incorporated in 1546.

A "Low Town" has grown at the foot of the cliff beyond the Severn, here crossed by a bridge which is the successor of others dating back probably to Saxon times. The name of the town may refer to the former existence of another bridge at Quatford to the south. There are numerous half-timbered buildings, including Bishop Percy's birthplace (1580) and the town hall (removed from another site in 1652); and many houses have cellars cut in the rock. The chief industries of the town are now carpet-weaving, worsted-dyeing and malting, but lace and stockings were formerly made, and boat-building flourished in connection with barge traffic on the Severn with Shrewsbury and Bristol. The town was also a rival to Shrewsbury in the cloth and hide trades. Of the two parish churches St. Mary's was erected by Telford about 1800, while St. Leonard's was practically rebuilt in 1862.

The borough returned two members to parliament from 1295 to 1867. It now forms part of the Ludlow parliamentary division of Shropshire. It is governed by a mayor, four aldermen and 12 councillors. Area 3,018 acres.

**BRIDGWATER**, seaport and municipal borough, Somerset, England. Pop. (1931) 17,139. It lies in the level country east of the Quantock Hills, on the River Parret, 10m. from its mouth; and its two portions are connected by an iron bridge. The settlement (Briges, Briggewalteri, Brigewauter) is probably Saxon in origin, owing its growth to a favourable position on the chief river of Somerset. It became a free borough, having a Saturday market and an annual fair, by a charter of 1201. Fairs for the sale of wool and wine were important in mediaeval times. Numerous charters were granted in the 14th century, and the borough was incorporated in 1468. The trade of the port revived after the construction of the new dock in 1841. The principal church is that

of St. Mary Magdalene, in part of 14th century date. The town was the birthplace of Admiral Blake (1598). Five miles to the south-east is Sedgemoor, a marshy tract where the Monmouth rebellion was crushed in 1685. The river is navigable to the town for vessels of 200 tons, but is liable to a bore which sometimes attains nine feet. There is a considerable coasting trade, the chief article of export being bath bricks, in which the town has a monopoly. They are made of the mingled sand and clay deposited by the tides. Farm produce, earthenware and cement are also exported, while coal and timber are imported. There is a station on the G.W. and Somerset and Dorset railways. The town is governed by a mayor, six aldermen and 18 councillors. Area 930 ac. It is included in the Bridgwater parliamentary county division.

**BRIDLINGTON**, municipal borough, East Riding of Yorkshire, England, 31m. N.N.E. of Hull by a branch of the L.N.E.R. Pop. (1931) 19,704. It is divided into two parts, the ancient market town lying about 1m. from the coast, while the modern houses of Bridlington Quay, the watering-place, fringe the shore of Bridlington bay. Southward the coast becomes low, but northward it is steep and very fine, where the great spur of Flam-borough head (q.v.) projects eastward. Bridlington seems to have been a borough before the Conquest, as mention of its burgesses occurs in Domesday. Its mediaeval history is linked up with its markets and fairs, first mentioned in a grant of 1200, and its port, first mentioned in Stephen's reign. In the old town the church of St. Mary and St. Nicholas consists of the fine Decorated and Perpendicular nave, with Early English portions, of the priory church of an Augustinian foundation of the time of Henry I. There remains also the Perpendicular gateway, serving as the town hall. The founder of the priory was Walter de Gaunt, about 1114, and the institution flourished until 1537. Bridlington was an early centre of Nonconformity, and a Congregational society was founded in 1662. In the late 18th century it became fashionable with a chalybeate spring. The new developments took place around Bridlington Quay, now the centre of attraction for visitors. Bridlington was created a municipal borough in 1899 and has an area of 2,746 ac. It is in the Buckrose parliamentary division.

**BRIDPORT, ALEXANDER HOOD, VISCOUNT** (1727-1814), British admiral, was the younger brother of Samuel, Lord Hood. Entering the navy in Jan. 1741, he was appointed lieutenant of the "Bridgewater" six years later, and served under Saunders in the Mediterranean and under Hawke at Quiberon Bay (Nov. 20, 1759). He was present in the "Robust," at the battle of Ushant in 1778, and gave evidence against Keppel in the court-martial which followed this action. Two years later he was made rear-admiral of the white, and succeeded Kempenfeldt as one of Howe's flag-officers, and in the "Queen" he was present at the relief of Gibraltar in 1782. On the outbreak of the war with France in 1793 Sir Alexander Hood, as Howe's second in command, shared in the operations which culminated in the "Glorious First of June," and for his services was made Baron Bridport of Cricket St. Thomas, in Somerset, in the Irish peerage. Henceforth Bridport was practically in independent command. In 1795 he fought the much-criticized partial action of June 23 off Belle-Ile. His peerage was made English, and he became vice-admiral of England. In 1796-97 he practically directed the war from London. In the following year he was about to put to sea when the Spithead fleet mutinied. After this Bridport took the fleet to sea as commander-in-chief in name as well as in fact, and from 1798 to 1800 personally directed the blockade of Brest. In 1800 he was relieved by St. Vincent, and retired from active duty. The viscounty in the English peerage died with him; the Irish barony passed to the younger branch of his brother's family, for whom the viscounty was re-created in 1868.

See Charnock, *Biographia Navalis*, vi. 153; *Naval Chronicle*, i. 265; *Ralfs, Nav. Biog.*, i. 202.

**BRIDPORT**, municipal borough, Dorsetshire, England, 15m. W. of Dorchester on a branch of the G.W. railway. Pop. (1931) 5,917. It takes its name from the small river Brit. The main part of the town is about a mile from the sea, but is connected

therewith by a winding street ending at the fishing village of West Bay.

Bridport was of some importance before the Conquest, when it consisted of 120 houses rated for all the king's services. The town is first mentioned as a borough in the Pipe Roll of 1180. Charters were granted in the 13th century and markets seem to have been held from the same time. It was incorporated by James I. in 1619, but Charles II. granted a new charter which held until 1835. As early as 1213 the town was noted for the manufacture of ropes and cables. The royal navy procured its hawsers, etc., from Bridport in the 16th century. At the present time sailcloth, cordage linen and fishing-nets are manufactured for export. There is some import trade in flax, timber and coal, but the harbour is accessible only to small vessels. The municipal borough is under a mayor, six aldermen and 18 councillors. Area 672 acres. It is included in the western division of the county of Dorset for purposes of parliamentary representation.

**BRIE**, an agricultural district of north France, to the east of Paris, bounded west and south by the Seine, north by the Marne. Area about 2,400 square miles. It includes most of the department of Seine-et-Marne, with portions of Seine, Seine-et-Oise, Aisne, Marne and Aube. The western half was known as the *Brie française*, the eastern as the *Brie champenoise*. It varies in altitude between 300 and 500ft. in the west, and between 500 and 650ft. in the east. The region includes the Forêt de Senart, the Forêt de Crécy and the Forêt d'Armainvilliers. The surface soil is clay with embedded fragments of siliceous sandstone, used for millstones and constructional purposes; the subsoil is limestone. The Yères, a tributary of the Seine, and the Grand Morin and Petit Morin, tributaries of the Marne, are the chief rivers, but the region is not very well watered and the rainfall is only between 20 and 24 inches. The Brie is famous for its grain and its dairy products, especially cheese.

**BRIEF**, a statement prepared by a solicitor for the use of counsel at the trial of a cause with the "proofs" of witnesses, if any. Accompanying the brief may be copies of the pleadings (*see PLEADING*), and of all documents material to the case. The brief is always endorsed with the title of the court in which the action, is to be tried, with the title of the action, and the names of the counsel and of the solicitor who delivers the brief. Counsel's fee is also marked. The delivery of a brief to counsel gives him authority to act for his client in all matters relevant to the case. The result of the action is noted on the brief by counsel, or, if the action is compromised, the terms of the compromise are endorsed on each brief and signed by the leading counsel on the opposite side. In Scotland a brief is called a memorial.

In the United States the word has, to a certain extent, a different meaning, a brief in its English sense not being required, for the American attorney exercises all the functions distributed in England between barristers and solicitors. A lawyer sometimes prepares for his own use what is called a "trial brief" for use at the trial. This corresponds in all essential particulars with the English "brief." But the more distinctive use of the term in America is that of the brief "in error or appeal," before an appellate court. This is a written or printed document embodying the argument on the case. Most of the appellate courts require the filing of printed briefs for the use of the court and opposing counsel. In the United States Supreme Court and circuit courts of appeal the brief is required to contain a concise statement of the case, a specification of errors relied on, including the substance of evidence, the admission or rejection of which is to be reviewed, or any extract from a charge excepted to, and an argument exhibiting clearly the points of law or fact to be discussed. This form of brief is also adopted for use at the trial in certain states of the Union which require printed briefs to be delivered to the court.

The *brief-bag*, in which counsel's papers are carried to and from court, now forms part of a barrister's outfit, but in the early part of the 19th century the possession of a brief-bag was strictly confined to those who had received one from a king's counsel. King's counsel were then few in number, and had a salary of £40 a year, with a supply of paper, pens and purple bags. These bags they distributed among rising juniors of their acquaintance,

whose bundles of briefs were getting inconveniently large to be carried in their hands. These perquisites were abolished in 1830. English brief-bags are now either blue or red. Blue bags are those with which barristers provide themselves on their call, and it is a breach of etiquette to let this bag be visible in court. The only brief-bag allowed to be placed on the desks is the red bag, which by the etiquette of the Bar is given by a leading counsel to a junior who has been useful to him in some important case. In the United States the brief-bag is green.

**BRIEG**, a town of Germany, in Prussian Silesia, on the left bank of the Oder, 27m. S.E. of Breslau. Pop. (1925) 27,424. Brieg (*Civitas Altae Ripae*), obtained municipal rights in 1250 from Duke Henry III. of Breslau, and was fortified in 1297; its name is derived from the Polish *Brzeg* (shore). Burned by the Hussites in 1428, but soon rebuilt, it was again fortified by Joachim Frederick, duke of Brieg, in 1595, and suffered severely in the wars of the subsequent centuries. From 1311 to 1675 Brieg was the capital of an independent line of dukes, by one of whom the castle was built in 1341. On the death of the last duke in 1675 the duchy was annexed by Austria, and eventually fell to Prussia with Silesia in 1742. The fortifications of the town, now marked by handsome promenades, were destroyed by the French in 1807. It has a Renaissance castle, formerly the residence of the counts of Brieg. It is an agricultural centre with important cattle-markets. Metal-work, soap, wire-goods, cement and pianos are also produced.

**BRIELLE**, in the province of South Holland, Holland. Pop. (1927) 3,626. It has a long sea-faring tradition and a large number of its inhabitants are fishermen or pilots. It was captured in 1572 by the *Gueux sur Mer*, a band of privateers raiding the Dutch coast under commission of the prince of Orange. It was the home of the admirals Van Tromp and Van Almonde. There is a quaint town hall and an orphanage dating from 1533, while the tower of the Groote Kerk of St. Catherine serves as a lighthouse. Brielle lost its trade to Hellevoetsluis through the cutting of the Voornsche canal in 1829.

**BRIENNE-LE-CHÂTEAU**, a town of north-eastern France, department of Aube, 1m. from the Aube and 26m. N.E. of Troyes. Pop. (1926) 1,625. The château, which overlooks the town, was built in the 18th century by Cardinal de Brienne (*q.v.*). The church dates from the 16th century and contains good stained glass. In 1814 Brienne was the scene of fighting between Napoleon and the Allies. Brewing is carried on.

**Counts of Brienne**.—Under the Carolingian dynasty Brienne-le-Château was the capital town of a French countship. In the 10th century it was captured by two adventurers named Engelbert and Gobert, and from the first of these sprang the noble house of Brienne, which played an important part in history in the 13th century.

**BRIENZ, LAKE OF**, Canton Berne, Switzerland, an expansion of the Aar, 9m. long, 1½m. wide, 856ft. maximum depth, 11½ sq. m. area, surface 1,857ft. above sea. It is gloomy and in a deep hollow with Brienz on the east and Bönigen on the west. The Giessbach falls are on the south shore, and small villages on the north shore (*see* THUN, LAKE OF). Its chief affluent is the Lütschine from Grindelwald.

**BRIERLEY, BENJAMIN** (1825–1896), English weaver and writer in Lancashire dialect. He started in 1869 *Ben Brierley's Journal*, a weekly, which continued till 1891, and he gave public readings from his own writings, visiting America in 1880 and 1884. His sketches, produced under the name of "Ab-o'-th'-Yate" (about America, London, etc.), and his pictures of Lancashire common life were collected after his death. He died on Jan. 18, 1896.

**BRIERLY, SIR OSWALD WALTERS** (1817–1894), English marine painter, was born at Chester. He exhibited some drawings of ships at the Royal Academy in 1830. In 1841 he started round the world with Benjamin Boyd (1796–1851), in the latter's ship "Wanderer," and made his home at Auckland for ten years. Brierly Point is called after him. He sailed on H.M.S. "Rattlesnake" in 1848, and with Sir Henry Keppel on the "Meander" in 1850, he returned to England in 1851 on this ship, and

illustrated Keppel's book about his cruise (1853). Brierly was attached to the suites of the duke of Edinburgh and the prince of Wales on their tours by sea and in 1874 he was made marine-painter to the queen. His more important works include the historical pictures, "The Retreat of the Spanish Armada" (1871) and "The Loss of the Revenge" (1877). In 1885 he was knighted, and he died on Dec. 14, 1894.

**BRIEUX, EUGÈNE** (1858– ), French dramatist, was born in Paris of poor parents. A one-act play, *Bernard Palissy*, written in collaboration with M. Gaston Salandri, was produced in 1879, but he had to wait 11 years before he obtained another hearing, his *Ménage d'artistes* being produced by Antoine at the Théâtre Libre in 1890. His plays are essentially didactic, being aimed at some weakness or iniquity of the social system. *Blanchette* (1892) pointed out the evil results of education of girls of the working-classes; *M. de Réboval* (1892) was directed against pharisaism; *L'Engrenage* (1894) against corruption in politics; *Les Bienfaiteurs* (1896) against the frivolity of fashionable charity; and *L'Évasion* (1896) satirized an indiscriminate belief in the doctrine of heredity. *Les Trois Filles de M. Dupont* (1897) is a powerful, somewhat brutal study of the miseries imposed on poor middle-class girls by the French system of dowry; *Le Résultat des courses* (1898) shows the evil results of betting among the Parisian workmen; *La Robe rouge* (1900) was directed against the injustices of the law; *Les Remplaçantes* (1901) against the practice of putting children out to nurse. *Les Avaries* (1901), forbidden by the censor, on account of its medical details, was read privately by the author at the Théâtre Antoine; and *Petite amie* (1902) describes the life of a Parisian shop-girl. Later plays are *La Couvée* (1903, acted privately at Rouen in 1893); *Maternité* (1904); *Les Hammetons*, a comedy in three acts (1916); *Suzette* (1909); *La femme seule* (1913); *Les Américains chez nous* (1920); *Puisque je t'aime* (1929). *See also* *Théâtre complet de Brieux* (1921–1928).

**BRIG** (Fr. *Brigue*, Ital. *Briga*), a town in the Swiss canton of the Valais, situated at the foot of the northern slope of the Simplon pass, south of the Rhone. Its older houses are very Italian in appearance, while its most prominent buildings (castle, former Jesuits' college and Ursuline convent) all date from the 17th century, and are due to the generosity of a member of the local Stockalper family. The prosperity of Brig was bound up with the Simplon pass (*q.v.*) so that it gradually supplanted the ancient village of Naters opposite, becoming a separate parish in 1517. Its mediaeval name was *Briga dives*. The opening of the carriage road across the Simplon (1807) and of the tunnel (1906), as well as the development of the tourist industry in the Upper Valais, have increased the importance and size of the town. The opening of the Lötschberg tunnel beneath the Lötschen pass (1913) affording direct communication between Milan and Berne and the Bernese Oberland, has further contributed to its prosperity.

It is an important frontier station on the international railway from Paris through Lausanne (or Berne) to Italy. Pop. (1920) 3,132, almost all Roman Catholic and 2,342 German-speaking, 401 French-speaking and 387 Italian-speaking.

*See Dict. hist. et biogr. de la Suisse*, ii.

**BRIGADE**, a unit in military organization commanded by a major-general, brigadier or colonel, and composed of two or more regiments of infantry, cavalry or artillery (Fr. and Ger. *brigade*, Ital. *brigata*, Span. *brigada*; the English use of the word dates from the early 17th century). The British infantry brigade consists as a rule of four battalions with supply, transport and medical units attached; the cavalry brigade of three regiments of cavalry. An artillery "brigade" is in Great Britain a smaller unit, forming a lieutenant-colonel's command and consisting of four batteries. (*See* ARMY, ARTILLERY, INFANTRY and CAVALRY.) The staff of an infantry or cavalry brigade in peace consists of the brigadier (*q.v.*) commanding, and the brigade-major, a staff-officer whose duties are intermediate between those of an adjutant and those of a general staff officer. In war, a staff captain is added for administrative duties, as well as various specialist officers, *e.g.*, intelligence, machine-gun, transport.

**BRIGADIER**, a military rank conferred by Louis XIV. upon the commander of several regiments. The British copied it from the French very early and a Royal warrant of 1699 states that "the Major General of Our Ordnance within our Kingdom for the time being shall have rank and precedence as Brigadier," evidence that the title was stabilized at that date. In fact the corporals of the Life Guards in 1679 were commissioned officers, their rank being "eldest Lieutenants of horse" but they were generally styled brigadiers. In the French army at present a "brigadier" is a corporal (*i.e.*, an N.C.O.). In the British service the rank of brigadier-general (held by the officer commanding a brigade of cavalry or infantry, or an equivalent staff appointment) was abolished just after the World War, being superseded by "colonel-commandant," but since 1928 "colonel-commandant" has been abolished and superseded by "brigadier."

See F. Grose *Military Antiquities* (1812); J. Sibbald Scott *The British Army* (1868-80).

**BRIGANDAGE.** The brigand is the outlaw who conducts warfare by skirmishes and surprises; who makes the war support itself by plunder, by extorting blackmail, by capturing prisoners and holding them to ransom; who enforces his demands by violence, and kills the prisoners who cannot pay. Brigandage may be, and not infrequently has been, the last resource of a people subject to invasion. Italy and Spain suffered for a long time from the disorder developed out of the popular resistance to the Napoleonic invasions. Numbers of guerilla warriors of both countries, who in normal conditions might have been honest, had acquired a preference for living by brigandage, which they could not resign when the enemy had retired.

The conditions which favour the development of brigandage may be easily summed up. They are: first, bad administration; and, in a less degree, the possession of convenient hiding-places. But no forest, thicket nor mountain is a lasting protection against a good police, used with intelligence by the Government, and supported by the law-abiding part of the community. The great haunts of brigands in Europe have been central and southern Italy and the worst administered parts of Spain, except those which fell into the hands of the Moors. Such curable evils as the highwaymen of England, and their like in the United States, are not to be compared with the "Écorcheurs," or Skinners, of France in the 15th century, or the "Chauffeurs" of the revolutionary epoch. The first were large bands of discharged mercenary soldiers who pillaged the country. The second were ruffians who forced their victims to pay ransom by holding their feet in fires. Both flourished because the Government was for the time disorganized by foreign invasion or by revolution.

The brigandage of Greece, southern Italy, Corsica and Spain had deep roots, and has never been quite suppressed. All four countries are well provided with natural hiding-places. In all the Administration has been bad, the law and its officers have been regarded as dangers, if not as deliberate enemies, so that they have found little native help, and, what is not the least important cause of the persistence of brigandage, there have generally been local potentates who found it to their interest to protect the brigand. In 1870 an English party, consisting of Lord and Lady Muncaster, Mr. Vyner, Mr. Lloyd, Mr. Herbert and Count de Boyl, was captured at Oropos, near Marathon, and a ransom of £25,000 was demanded. Lord and Lady Muncaster were set at liberty to seek for ransom, but the Greek Government sent troops in pursuit of the brigands, and the other prisoners were then murdered. The scoundrels were hunted down, caught and executed. In Aug. 1928 two former Greek deputies, M. M. Meles and Milonas, were captured by brigands in Epirus and ransomed for a considerable sum. In the Balkans, under Turkish rule, brigandage continued to exist in connection with the Christian revolt against the Turk, and the race conflicts of Albanians, Walachians, Pomuks, Bulgarians and Greeks. In Corsica the "maquis" has never been without its brigand hero, because industry has been stagnant, family feuds persist, and the Government has never quite succeeded in persuading the people to support the law. The brigand is always a hero to at least one faction of Corsicans.

The conditions which favour brigandage have been more prevalent, and for longer, in Italy than elsewhere in western Europe, with the standing exception of Corsica, which is Italian in all but political allegiance. Until the middle of the 19th century Italy was divided into small States, so that the brigand who was closely pursued in one could flee to another. Thus it was that Marco Sciarra of the Abruzzi, when hard-pressed by the Spanish viceroy of Naples—just before and after 1600—could cross the border of the papal States and return on a favourable opportunity. When Pope and viceroy combined against him, he took service with Venice, whence he could communicate with his friends at home, and pay them occasional visits. On one such visit he was led into a trap and slain. Marco Sciarra had terrorized the country far and wide at the head of 600 men. He was the follower and imitator of Benedetto Mangone, of whom it is recorded that, having stopped a party of travellers which included Torquato Tasso, he allowed them to pass unharmed out of his reverence for poets and poetry. Mangone was finally taken, and beaten to death with hammers at Naples. He and his like are the heroes of much popular verse, written in *ottava rima* and beginning with the traditional epic invocation to the muse.

In Naples the Bourbon dynasty reduced brigandage very much, and secured order on the main high-roads. But it was not extinguished, and it revived during the French invasion. When Ferdinand was restored on the fall of Napoleon, he employed an English officer, Gen. Sir Richard Church, to suppress the brigands. Gen. Church, who kept good order among his soldiers, and who made them pay for everything, gained the confidence of the peasantry, and restored a fair measure of security. It was he who finally brought to justice the villainous Don Ciro Anicchiarico—priest and brigand—who declared at his trial with offhand indifference that he supposed he had murdered about 70 people.

Every successive revolutionary disturbance in Naples saw a recrudescence of brigandage down to the unification of 1860-61, and then it was years before the Italian Government rooted it out. The source of the trouble was the support the brigands received from various kinds of *manutengoli* (maintainers)—great men, corrupt officials, political parties, and peasants who were terrorized, or who profited by selling the brigands food and clothes. What is true of Naples is true of other parts of Italy *mutatis mutandis*.

The history of brigandage in Spain is very similar. It may be said to have been endemic in and south of the Sierra Morena. In the north it has flourished when Government was weak, and after foreign invasion and civil wars. But it has always been put down easily by a capable Administration. It reached its greatest heights in Catalonia, where it began in the strife of the peasants against the feudal exactions of the landlords. It had its traditional hero, Roque Guinart, who figures in the second part of *Don Quixote*. The revolt against the house of Austria in 1640, and the War of the Succession (1700-14), gave a great stimulus to Catalan brigandage. But it was then put down in a way for which Italy offers no precedent. A country gentleman named Pedro Veciana, hereditary *balio* (military and civil lieutenant) of the archbishop of Tarragona in the town of Valls, armed his farm-servants, and resisted the attacks of the brigands. With the help of neighbouring country gentlemen he formed a strong band, known as the *Mozos* (Boys) of Veciana. The brigands combined to get rid of him by making an attack on the town of Valls, but were repulsed with great loss. The Government of Philip V. then commissioned Veciana to raise a special corps of police, the "escuadra de Cataluna." Since the organization of the excellent constabulary called "La Guardia Civil" by the Duke of Ahumada, about 1844, brigandage has been well kept down. More sympathy is felt for "bandoleros" in the south, and there also they find Spanish equivalents for the *manutengoli* of Italy.

On Oct. 8 1927 two French children were kidnapped by Moroccan brigands and their parents murdered. This outrage was followed a fortnight later by the capture of four French subjects, one of whom, M. Yves Steeg, was a nephew of the resident general of Morocco. The prisoners were only released on the payment of a considerable ransom on Nov. 17.

The "dacoits" or brigands of India were of the same stamp as their European colleagues. The Pindaris were more than brigands, and the Thugs (*q.v.*) were a religious sect.

**BIBLIOGRAPHY.**—The literature of brigandage, apart from pure romances or official reports of trials, is naturally extensive. Mr. McFarlane's *Lives and Exploits of Banditti and Robbers* (1837) is a useful introduction to the subject. The author saw a part of what he wrote about, and included in his work many references, particularly for Italy. A good bibliography of Spanish brigandage will be found in Eugenio de la Iglesia's *Reseña Histórica de la Guardia Civil* (1898). For actual pictures of the life, nothing is better than W. J. C. Moens' *English Travellers and Italian Brigands* (1866), and S. Soteropoulos' *The Brigands of the Morea*, translated by the Rev. J. O. Bagdon (1868).

**BRIGANDINE**, a French word meaning the armour for the *brigandi* or *brigantes*, light-armed foot soldiers; part of the armour of a foot soldier in the middle ages, consisting of a padded tunic of canvas, leather, etc., and lined with closely sewn scales or rings of iron.

**BRIGANTES**, a people of northern Britain, who inhabited the country from the mouth of the Humber on the east, and Mersey on the west, as far northwards as the Wall of Antoninus. Their chief town was *Eboracum* (or *Eboracum*; York). They first came into contact with the Romans during the reign of Claudius, when they were defeated by Publius Ostorius Scapula. Under Vespasian they submitted to Petillius Cerealis, but were not finally subdued till the time of Antoninus Pius (*Tac. Agricola*, 17; *Pausan.* viii. 43. 4). A branch of the Brigantes also settled in the south-east corner of Ireland, near the river Bircus (Barrow). The name Brigantes is said to mean "mountaineers."

See A. Holder, *Altceltischer Sprachschatz*, i. (1896), for ancient authorities; J. Rhys, *Celtic Britain* (3rd ed., 1904); Pauly-Wissowa, *Realencyklopädie*, iii. pt. i. (1897).

**BRIGG** (properly GLANFORD BRIGG or GLAMFORD BRIDGE), urban district of Lindsey (north Lincolnshire), England, situated on the river Ancholme, which affords water communication with the Humber. Pop. (1931) 4,019. It is 23 m. by road north of Lincoln, and is served by the L.N.E. railway. Trade is principally agricultural.

**BRIGGS, CHARLES AUGUSTUS** (1841–1913), American Hebrew scholar and theologian, was born in New York city, Jan. 15, 1841. He was educated at the University of Virginia, the Union Theological Seminary, and the University of Berlin. After a pastorate in the Presbyterian church of Roselle (N.J.), he went to the Union Theological seminary, where he held successively three different professorships. In 1892 he was tried for heresy by the presbytery of New York and acquitted. The General Assembly, to which the case was appealed, suspended Dr. Briggs in 1893, being influenced, it would seem, in part, by what his colleagues called the "dogmatic and irritating" nature of his inaugural address. He was ordained a priest of the Protestant Episcopal Church in 1900. With S. R. Driver and Francis Brown he prepared a revised *Hebrew and English Lexicon* (1891–1905), and with Driver edited the *International Critical Commentary*. His publications include *Biblical Study* (1883); *American Presbyterianism* (1885); *Messianic Prophecy* (1886); *Whither? A Theological Question for the Times* (1889); *The Bible, the Church and the Reason* (1892); *New Light on the Life of Jesus* (1904); *A Critical and Exegetical Commentary on the Book of Psalms* (1906–07), in which he was assisted by his daughter; *Church Unity* (1909); *The Fundamental Christian Faith* (1913); and, posthumously, *Theological Symbolics* (1914). He died in New York, on June 8, 1913.

**BRIGGS, HENRY** (1556–1630), English mathematician, was born at Warley Wood, near Halifax, in Yorkshire. He graduated at St. John's college, Cambridge, in 1581, and obtained a fellowship in 1588. In 1592 he was made reader of the physical lecture founded by Dr. Thomas Linacre, and in 1596 first professor of geometry in Gresham House (afterwards College), London. In his lectures at Gresham House he proposed the alteration of the scale of logarithms from the hyperbolic form which John Napier had given them, to that in which unity is assumed as the logarithm of the ratio of ten to one. In conferences with Napier the alteration proposed by Briggs was agreed upon; and

on his return from his second visit to Edinburgh in 1617 he accordingly published the first chiliad of his logarithms. (*See* NAPIER, JOHN.) In 1619 he was appointed Savilian professor of geometry at Oxford. In 1622 he published a small tract on the *North-West Passage to the South Seas, through the Continent of Virginia and Hudson's Bay*; and in 1624 his *Arithmetica Logarithmica*, in folio, a work containing the logarithms of 30,000 natural numbers to 14 places of figures besides the index. He also completed a table of logarithmic sines and tangents for the hundredth part of every degree to 14 places of figures besides the index with a table of natural sines to 15 places, and tangents and secants for the same to ten places; all of which were printed at Gouda in 1631 and published in London in 1633 under the title of *Trigonometria Britannica* (*see* TABLE, MATHEMATICAL). Briggs died on Jan. 26, 1630.

Other works are: *A Table to find the Height of the Pole, the Magnetic Declination being given* (1602); "Tables for the Improvement of Navigation," printed in the second edition of Edward Wright's treatise entitled *Certain Errors in Navigation detected and corrected* (1610); *A Description of an Instrumental Table to find the part proportional, devised by Mr. Edward Wright* (1616 and 1618); *Euclidis Elementorum VI. libri priores* (1620); *A Treatise on the North-West Passage to the South Sea* (1622), reprinted in Purchas's *Pilgrims*, vol. iii. p. 852; *Mathematica ab Antiquis minus cognita*. Some other works, as his *Commentaries on the Geometry of Peter Ramus*, and *Remarks on the Treatise of Longomontanus respecting the Quadrature of the Circle*, have not been published.

**BRIGHAM**, a city in northern Utah, U.S.A., near the Bear river bay of Great Salt lake, 20m. N. of Ogden; the county seat of Box Elder county. It has an elevation of 4,307ft. and lies at the mouth of the canyon formed by Box Elder creek. It is on Federal Highway 91, and is served by the Southern Pacific and the Union Pacific railways. The population in 1930 was 5,093. Brigham was settled in 1853 by Mormons, who by irrigation transformed the sagebrush desert into a garden. The region is famous for its peaches and other fruits, and the city itself is practically a huge orchard, with an irrigating ditch along every street. On Peach Day, early in September, fruit is given freely to the thousands of visitors. Among the manufacturing industries are large tomato canneries and beet sugar mills. The Bear river bay marshes are one of the noted bird grounds of the country, attracting both sportsmen and students. Brigham was incorporated as a city in 1867, and in 1918 adopted a city manager form of government.

**BRIGHOUSE**, municipal borough, West Riding, Yorkshire, England, 5½m. N. of Huddersfield by the L.M.S. Railway, on the river Calder. Population (1931) 19,756. It has large woollen and worsted factories. Much of the machinery and many tools used in the textile industry are made locally. Iron founding, especially moulding, quarry working and chemical dye mixing are pursued. The town was incorporated in 1893 and is governed by a mayor, eight aldermen and 24 councillors. Brighouse is in the Elland parliamentary division of Yorkshire (West Riding). Area of municipal borough, 2,231 acres.

**BRIGHT, SIR CHARLES TILSTON** (1832–1888), English telegraph engineer, who came of an old Yorkshire family, was born on June 8, 1832, at Wanstead, Essex. At the age of 15 he became a clerk under the Electric Telegraph Company. In 1852 he was appointed engineer to the Magnetic Telegraph Company, and superintended the laying of lines in various parts of the British Isles, including in 1853 the first cable between Great Britain and Ireland, from Portpatrick to Donaghadee. His experiments convinced him of the practicability of an electric submarine cable connection between Ireland and America; and having in 1855 already discussed the question with Cyrus Field, who with J. W. Brett controlled the Newfoundland Telegraph Company on the other side of the ocean, Bright organized with them the Atlantic Telegraph Company in 1856 for the purpose of carrying out the idea, himself becoming engineer-in-chief. The story of the first Atlantic cable is told elsewhere (*see* TELEGRAPH), and it must suffice here to say that in 1858, after two disappointments, Bright successfully accomplished what to many had seemed an impossible feat. Within a few days of landing the Irish end of the line at Valentia he was knighted in Dublin. Subsequently Bright super-

vised the laying of submarine cables in various regions of the world, and took a leading part as pioneer in other developments of the electrical industry. In conjunction with Josiah Latimer Clark, with whom he entered into partnership in 1861, he invented improved methods of insulating submarine cables, and a paper on electrical standards read by them before the British Association in the same year led to the establishment of the British Association committee on that subject, whose work formed the foundations of the system still in use. From 1865 to 1868 he was Liberal M.P. for Greenwich. He died on May 3, 1888, at Abbey Wood, near London.

See *Life Story of Sir C. T. Bright*, by his son Charles Bright (revised ed. 1908).

**BRIGHT, JOHN** (1811-1889), British statesman, was born at Rochdale on Nov. 16, 1811 of Quaker stock. His father, Jacob Bright had started a cotton-mill at Rochdale in 1809; his mother, Martha Wood, Jacob Bright's second wife, was a woman of great strength of character and refined taste. John being a delicate child, was sent as a day-scholar to a boarding-school near his home. A year at the Ackworth school, two years at a school at York, and a year and a half at Newton, near Clitheroe, completed his education. He learned, he himself said, but little Latin and Greek, but acquired a love of English literature. In his 16th year he entered his father's mill, and in due time became a partner in the business. Two agitations were then going on in Rochdale—the first (in which Jacob Bright was a leader) in opposition to a local church-rate, and the second for parliamentary reform, by which Rochdale successfully claimed to have a member allotted to it under the Reform bill. In both these movements John Bright took part. He was an ardent Nonconformist, proud to number among his ancestors John Gratton, a friend of George Fox, and one of the persecuted and imprisoned preachers of the Society of Friends. His political interest was probably first kindled by the Preston election in 1830, in which Lord Stanley, after a long struggle, was defeated by "Orator" Hunt. Bright was one of the founders of the Rochdale Literary and Philosophical Society, took a leading part in its debates, and on returning from a holiday journey in the East, gave the society a lecture on his travels. He first met Richard Cobden in 1836 or 1837. Cobden urged him to speak against the Corn laws. His first speech on the Corn laws was made at Rochdale in 1838, and in the same year he joined the Manchester provisional committee which in 1839 founded the Anti-Corn Law league. He was still only the local public man, taking part in all public movements, especially in opposition to John Feilden's proposed factory legislation, and to the Rochdale church-rate. In 1839 he married Elizabeth, daughter of Jonathan Priestman of Newcastle-on-Tyne. A daughter, Helen, was born to them; but the young wife, after a long illness, died of consumption in Sept. 1841. Three days after her death at Leamington, Cobden called to see him. Cobden spoke some words of condolence, but "after a time he looked up and said, 'There are thousands of homes in England at this moment where wives, mothers and children are dying of hunger. Now, when the first paroxysm of your grief is past, I would advise you to come with me, and we will never rest till the Corn laws are repealed.' I accepted his invitation," added Bright, "and from that time we never ceased to labour hard on behalf of the resolution which we had made."

At the general election in 1841 Cobden was returned for Stockport, and in 1843 Bright was the Free Trade candidate at a by-election at Durham. He was defeated, but his successful competitor was unseated on petition, and at the second contest Bright was returned. He took his seat in the House of Commons on July 28, 1843 in an atmosphere of suspicion and hostility, due to the reputation he had gained in the last two years as the most formidable agitator against the Corn laws. Wherever John Bright was announced as the speaker vast crowds assembled, for he had the passion which Cobden lacked. His "more stately genius," as Mr. John Morley called it, was already making him the undisputed master of the feelings of his audiences. In the House of Commons his progress was slower. Cobden's argumentative speeches were regarded more sympathetically than Bright's more

rhetorical appeals, and in a debate on Villiers's annual motion against the Corn laws Bright was heard with so much impatience that he was obliged to sit down. In the next session (1845) he moved for an inquiry into the operation of the Game laws. At a meeting of county members earlier in the day Peel had advised them not to be led into discussion by a violent speech from the member for Durham, but to let the committee be granted without debate. Bright was not violent, and Cobden said that he did his work admirably, and won golden opinions from all men. The speech established his position in the House of Commons.

In this session Bright and Cobden came into opposition, Cobden voting for the Maynooth Grant and Bright against it. On only one other occasion—a vote for South Kensington—did they go into opposite lobbies during twenty-five years of parliamentary life. In the autumn of 1845 Bright retained Cobden in the public career to which Cobden had invited him four years before. Bright was in Scotland when a letter came from Cobden announcing his determination, forced on him by business difficulties, to retire from public work. Bright replied that if Cobden retired the mainspring of the league was gone, and a few days later set off for Manchester, posting in that wettest of autumns through "the rain that rained away the Corn laws." On his arrival he raised the money which tided Cobden over the emergency. The crisis of the struggle had come. The bad harvest and the potato disease drove him to the repeal of the Corn laws, and at a meeting in Manchester on July 2, 1846 Cobden moved and Bright seconded a motion dissolving the league. A library of twelve hundred volumes was presented to Bright as a memorial of the struggle.

Bright married, in June 1847, Margaret Leatham, of Wakefield, by whom he had seven children. In the succeeding July he was elected for Manchester, with Milner Gibson, without a contest. In the new parliament, as in the previous session, he opposed legislation restricting the hours of labour, and as a Nonconformist, spoke against clerical control of national education. In 1848 he voted for Hume's household suffrage motion, and introduced a bill for the repeal of the Game laws. When Lord John Russell brought forward his Ecclesiastical Titles bill, Bright opposed it as "a little, paltry, miserable measure," and foretold its failure.

In a speech in favour of the government bill for a rate in aid in 1849, he won loud cheers from both sides, and was complimented by Disraeli for having sustained the reputation of that assembly. From this time forward he had the ear of the House, and took effective part in the debates. He spoke against capital punishment, against church-rates, against flogging in the army, and against the Irish Established Church. He supported Cobden's motion for the reduction of public expenditure, and in and out of parliament pleaded for peace. In the election of 1852 he was again returned for Manchester on the principles of free trade, electoral reform and religious freedom. But war was in the air, and the most impassioned speeches he ever delivered were addressed to this parliament in fruitless opposition to the Crimean war. Neither the House nor the country would listen. "I went to the House on Monday," wrote Macaulay in March 1854, "and heard Bright say everything I thought; and I heard Palmerston and Graham expose themselves lamentably." His most memorable speech, the greatest he ever made, was delivered on Feb. 23, 1855. "The angel of death has been abroad throughout the land. You may almost hear the beating of his wings," he said, and concluded with an appeal to the prime minister that moved the House as it had never been moved within living memory.

Bright was disqualified by illness during the whole of 1856 and 1857. In Palmerston's penal dissolution in the latter year, Bright was rejected by Manchester, but in August, while ill and absent, Birmingham elected him without a contest. He returned to parliament in 1858, and in February seconded the motion which threw out Lord Palmerston's government. Lord Derby thereupon came into office for the second time, and Bright had the satisfaction of assisting in the passing of two measures which he had long advocated—the admission of Jews to parliament and the transfer of the government of India from the East India Company to the

Crown. In October he addressed his new constituents, and started a movement for parliamentary reform. He spoke at great gatherings at Edinburgh, Glasgow, Bradford and Manchester, and for the next nine years he was the protagonist of Reform. In the debates on the Reform bills submitted to the House of Commons from 1859 to 1867, Bright's was the most influential voice. He rebuked Lowe's "Botany Bay view," and described Horsman as retiring to his "political cave of Adullam," and hooking in Lowe. "The party of two," he said, "reminds me of the Scotch terrier, which was so covered with hair that you could not tell which was the head and which was the tail." These and similar phrases, such as the excuse for withdrawing the Reform bill in the year of the great budget of 1860—"you cannot get twenty wagons at once through Temple Bar"—were in all men's mouths. Bright's oratory constantly produced these popular cries. The phrase "a free breakfast table" was his; and on the rejection of Forster's Compensation for Disturbance bill he used the phrase as to Irish discontent, "Force is not a remedy."

During his great reform agitation Bright had vigorously supported Cobden in the negotiations for the treaty of commerce with France, and had taken the side of the North in the discussions in England on the American Civil War. He had a profound admiration for Abraham Lincoln, as an inscription written by him on a copy of Lincoln's portrait shows: "And if there be on earth and among men any 'Divine' right to govern, surely it rests with the Ruler so chosen and so appointed." (Dec. 4, 1861.) He believed that the government of the United States rested more than any other, on the free choice of a free people. No Englishman of his time was so outspoken on the Alabama case as Bright. It is interesting to read his conception of the future of the American continent. "I should say that if a man had a great heart within him, he would rather look forward to the day when, from that point of land which is habitable nearest to the Pole, to the shores of the Great Gulf, the whole of that vast continent might become one great confederation of States—without a great army and without a great navy, not mixing itself up with the entanglements of European politics, without a custom-house inside, through the whole length and breadth of its territory, and with freedom everywhere, equality everywhere, law everywhere, peace everywhere—such a confederation would afford at least some hope that man is not forsaken of Heaven, and that the future of our race may be better than the past." (Speech at Rochdale, Nov. 1861.) In March 1865 Cobden died, and Bright told the House of Commons he dared not even attempt to express the feelings which oppressed him, and sat down overwhelmed with grief. Their friendship was one of the most characteristic features of the public life of their time. "After twenty years of intimate and almost brotherly friendship with him," said Bright, "I little knew how much I loved him till I had lost him." In June 1865 parliament was dissolved, and Bright was returned for Birmingham without opposition. Palmerston's death in the early autumn brought Lord John Russell into power, and for the first time Bright gave his support to the government. Russell's fourth Reform bill was introduced, was defeated by the Adullamites, and the Derby-Disraeli ministry was installed. Bright declared Lord Derby's accession to be a declaration of war against the working classes, and roused the great towns in the demand for reform. Bright was the popular hero of the time. The winter of 1866-67 was the culminating point in his career as a political leader. The Disraeli Reform bill was carried. Lord Cranborne (3rd marquis of Salisbury), who had resigned from the Government when he saw the text of the Bill, remarked that "if the adoption of the principles of Mr. Bright be a triumph, then the Conservative party, in the whole history of its previous annals, has won no triumph so signal as this." In the autumn of 1868 Bright, with two Liberal colleagues, was again returned for Birmingham. Mr. Gladstone came into power with a programme of Irish reform in church and land such as Bright had long urged, and he accepted the post of president of the Board of Trade. He made a great speech on the second reading of the Irish Church bill, and wrote a letter on the House of Lords, in which he said, "In harmony with the nation they may go on for a long time, but throwing themselves athwart its course they

may meet with accidents not pleasant for them to think of." He also spoke strongly in the same session in favour of the bill permitting marriage with a deceased wife's sister. A severe illness compelled his retirement and kept him out of public life for four years. In August 1873 Mr. Gladstone reconstructed his cabinet, and Bright returned to it as chancellor of the duchy of Lancaster. But he was now an old man. In the election in January 1874 Bright and his colleagues were returned for Birmingham without opposition. When Mr. Gladstone resigned the leadership of his party in 1875, Bright was chairman of the party meeting which chose Lord Hartington as his successor. He took a less prominent part in political discussion, till the Eastern Question brought Great Britain to the verge of war with Russia, and his old energy flamed up afresh. In the debate on the vote of credit in February 1878, he urged the government not to increase the difficulties manufacturers had in finding employment for their workpeople by any single word or act which could shake confidence in business. The debate lasted five days. On the fifth day a telegram from Mr. Layard (afterwards Sir Austen, *q.v.*) was published announcing that the Russians were nearing Constantinople. In both Houses Mr. Layard's despatch was read, and in the excited Commons Mr. Forster's resolution opposing the vote of credit was withdrawn. Bright, however, distrusted the ambassador at the Porte, and gave reasons for doubting the alarming telegram. While he was speaking a note was put into the hands of Sir Stafford Northcote, and when Bright sat down he read it to the House. It was a confirmation from the Russian prime minister of Bright's doubts: "There is not a word of truth in the rumours which have reached you." At the general election in 1880 he was re-elected at Birmingham, and joined Mr. Gladstone's new government as chancellor of the duchy of Lancaster. For two sessions he spoke and voted with his colleagues; he supported Forster's Coercion bill in 1881, believing that without it a Land bill could not be got through parliament. But after the bombardment of the Alexandria forts he left the ministry and never held office again. He, however, gave a general support to Mr. Gladstone's government. In June 1883 he was the object of an unparalleled demonstration at Birmingham to celebrate his 25 years of service as its representative. At this celebration he spoke strongly of "the Irish rebel party," and accused the Conservatives of "alliance" with them, but withdrew the imputation when Sir Stafford Northcote moved that such language was a breach of the privileges of the House of Commons. At a banquet to Lord Spencer he accused the Irish members of having "exhibited a boundless sympathy for criminals and murderers." He refused in the House of Commons to apologize for these words, and was supported in his refusal by both sides of the House. At the Birmingham election in 1885 he stood for the central division of the redistributed constituency; he was opposed by Lord Randolph Churchill, but was elected by a large majority. In the new parliament he voted against the Home Rule bill, and in the election of 1886 which followed its defeat, when he was re-elected without opposition, his letters told with fatal effect against the Home Rule Liberals. He suggested that the Irish members should form a grand committee to which every Irish bill should go after first reading. But though he was himself a dissident, the break-up of the Liberal party filled him with gloom. His last speech at Birmingham was on March 29, 1888, at a banquet to celebrate Mr. Chamberlain's return from his peace mission to the United States. He spoke of Imperial federation as a "dream and an absurdity." In May his illness returned, he took to his bed in October, and died on March 27, 1889. He was buried in the graveyard of the meeting-house of the Society of Friends in Rochdale.

The 3rd marquess of Salisbury said of him, and it sums up his character as a public man: "He was the greatest master of English oratory that this generation—I may say several generations—has seen. . . . At a time when much speaking has depressed, has almost exterminated eloquence, he maintained that robust, powerful and vigorous style in which he gave fitting expression to the burning and noble thoughts he desired to utter."

See *Speeches on Parliamentary Reform* by John Bright, M.P., revised by Himself (1866); *Speeches on Questions of Public Policy*,

by John Bright, M.P., ed. J. E. Thorold Rogers (1868); *Public Addresses*, ed. J. E. Thorold Rogers (1879); G. Barnett Smith, *The Life and Speeches of the Right Hon. John Bright, M.P.* (1881); *Public Letters of the Right Hon. John Bright, M.P.*, collected by H. J. Leech (1885); Barry O'Brien, *John Bright* (1910); G. M. Trevelyan, *The Life of John Bright* (1913, 2nd ed. 1925).

**BRIGHT, RICHARD** (1789-1858), English physician, was born on Sept. 28, 1789, at Bristol. After an expedition to Iceland and a short period of study at Guy's hospital, London, Bright took his M.D. at Edinburgh in 1812. From 1814-15 he visited continental hospitals, and receiving his L.R.C.P. in 1816, became assistant physician to the London fever hospital. In 1820 he was made assistant physician at Guy's and four years later full physician. The results of his researches first appeared in *Reports of Medical Cases Selected with a View of Illustrating the Symptoms and Cure of Disease by a Reference to Morbid Anatomy* (1827), a work which described dropsical cases and showed that they involved a diseased condition of the kidney. "Bright's disease" soon became world-known, and its discoverer's reputation was ensured by subsequent papers on renal disease in the second volume of reports in 1831 (this also contained studies of the central nervous system and of diseases of the brain, meninges and cord) and in the important first volume of *Guy's Hospital Reports* of 1836. To these latter reports, from 1836 onwards, Bright contributed many papers on abdominal tumours, fever, diseased arteries of the brain, etc. He resigned his post at Guy's in 1843. He died in London on Dec. 16, 1858.

See *Guy's Hospital Reports, Bright Centenary Number* (1927).

**BRIGHTLINGSEA**, urban district, seaport and fishing station, Essex, England, on a creek of the Colne estuary, the terminus of a branch from Colchester (8 m.) of the L.N.E. railway. Pop. (1931) 4,145. The Colchester oyster-beds are mainly in this part of the Colne, and the oyster fishery is the chief industry. Boat-building is carried on, and the place is also a yachting centre. Brightlingsea, which appears in Domesday, is a member of the Cinque Port of Sandwich in Kent. Near the opposite shore of the creek is St. Osyth's priory, which originated as a nunnery founded by Osyth, a grand-daughter of Penda, king of Mercia; it became a foundation for Augustinian canons early in the 12th century. The remains, incorporated with a modern residence, include a late Perpendicular gateway—an embattled structure with flanking turrets.

**BRIGHTON**, Municipal, county and parliamentary borough, and seaside resort, Sussex, England, 51m. S. of London by the Southern railway. Pop. of county borough (1931) 147,427; of parliamentary borough, 188,914. Accessibility from the metropolis is the chief factor in its popularity. It is situated on the seaward slope of the south downs; the position is sheltered and the climate generally mild. The sea-front, one long promenade, overlooks the English Channel and stretches nearly four miles from Kemp Town on the east to Hove (a separate municipal borough) on the west. The extended borough (1927) includes Patcham, Rottingdean, Ovingdean and part of Falmer and Saltdean. Currents in the Channel opposite Brighton tend to drive the shingle eastward, and encroachments of the sea were frequent until the erection of a massive sea-wall, begun about 1830, 60 ft. high, 23 ft. thick at the base, and three ft. at the summit. Romans and Saxons occupied the site, but the earliest mention of Brighton (Bristelmeston, Bricelmestone, Brighthelmston) is the Domesday record that its three manors belonged to Earl Godwin. Two passed to the priories of Lewes and Michelham respectively. The third descended to the earls of Arundel, falling to the share of the duke of Norfolk in 1415, and being divided in 1502 between the families of Howard and Berkeley. Brighton was a large fishing village in 1086 with a rent of 4,000 herrings. In 1340 there were no merchants, only tenants of lands, but its prosperity increased during the 15th and 16th centuries, and it was assessed at £6 12s. 8d. in 1534. There is, however, no indication that it was a borough. In 1580 commissioners found that from time immemorial Brighton had been governed by two head boroughs sitting in the borough court, and assisted by a council called the Twelve. This constitution disappeared before 1772, when commissioners were appointed. Brighton became a parliamentary borough in 1832 and

was incorporated in 1854. From a fishing town in 1656 it became, 100 years later, a fashionable resort. Its popularity increased after the visit of the prince of Wales (see GEORGE IV.) to the duke of Cumberland in 1783, and was ensured by his building the Pavilion in 1784-87. His association with Mrs. Fitzherbert at Brighton was the starting-point of its fashionable repute. The Pavilion now contains a museum, art-galleries and assembly rooms. Some portions of the former parish church of St. Nicholas remain, but most churches and chapels are modern, and new parishes have been added. There are imposing institutions contributing to the entertainment of visitors. The aquarium site, with the exception of some fish tanks, was cleared and laid out as gardens in 1925. Preston and Queen's Park are the principal of several public recreation grounds, and Hollingbury Park, a large tract of downland north of the town, was bought before 1914. The race-course at Kemp Town is also the property of the town. Educational establishments are naturally numerous and include Brighton college, ranking as a public school. Building improvements and extensions are being made every year. There are two piers, of which the Palace pier, near the site of the old chain pier (1823) washed away in 1896, is near the centre of the town, while the West pier is towards Hove. Since 1921, facilities for landing steamer traffic have been improved. There are extensive mackerel and herring fisheries and motor engineering works. The parliamentary borough, which includes the parish of Hove, returns two members. The county borough was created in 1888. The municipal borough is under a mayor, 14 aldermen and 42 councillors.

**BRIGHTON**, a watering-place of Bourke county, Victoria, Australia. It is practically a suburb of Melbourne (*q.v.*). It has two piers and a growing population (*c.* 15,000).

**BRIGHT'S DISEASE**, a term in medicine applied to a class of diseases of the kidneys (acute and chronic nephritis) which have as their most prominent symptom the presence of albumen in the urine, often accompanied by dropsy. These associated symptoms in connection with kidney disease were first described in 1827 by Dr. Richard Bright, but instead of being, as was formerly supposed, the result of one form of disease of the kidneys, may be dependent on various morbid conditions (see KIDNEY DISEASES). Hence the term Bright's disease now has a generic application.

The symptoms of acute Bright's disease are severe. Pain in the back, vomiting and fever commonly usher in the attack. Dropsy, varying in degree from slight puffiness of the face to an accumulation of fluid sufficient to distend the whole body, and to occasion serious embarrassment to respiration, is a very common accompaniment. The urine is reduced in quantity, is of dark, smoky or bloody colour, and exhibits to chemical reaction the presence of a large amount of albumen, while, under the microscope, blood corpuscles and casts are found in abundance. Such a condition may supervene upon scarlatina or exposure to cold during drunkenness.

Acute inflammation may by its severity destroy life, or terminate in a chronic form of Bright's disease. On the other hand arrest of the inflammatory action frequently occurs, marked by increased amount of the urine, gradual disappearance of its albumen and other abnormal constituents, subsidence of the dropsy and rapid recovery of strength. Nevertheless recovery is rarely complete and relapses are common.

In the treatment of acute Bright's disease, good results are often obtained from local depletion, warm baths and the careful employment of diuretics and purgatives. Chronic Bright's disease is much less amenable to treatment, but efforts to spare the kidneys by restriction of nitrogenous food and by residence in a warm, dry climate (*e.g.*, Egypt) are indicated. (See KIDNEY, DISEASES OF, and ALBUMINURIA.)

**BRIGNOLES**, a town in south-east France, in the department of Var, 36m. by rail N.N.E. of Toulon. Pop. (1926) 4,030. It lies 754ft. above sea level, in the fertile valley of the Carami, contains an old palace of the counts of Provence, and has an active trade in olive oil, besides tanneries and bauxite mines.

**BRIHASPATI** or **BRAHMANASPATI** ("Lord of prayer"), a deity in the Vedic Hindu mythology, an ally of Indra

in his conquest of the cloud demon. In the *Rig Veda* he is identified with Agni (*q.v.*). Offspring of Heaven and Earth, he inspires prayer and protects the pious. Depicted as having seven mouths, 100 wings and sharp horns, he is armed with bow and axe, and his chariot is drawn by red horses. In the epics he is merely a priest or sage.

See A. A. Macdonell, *Vedic Mythology* (Strasbourg, 1897); E. W. Hopkins, *Epic Mythology* (Strasbourg, 1915).

**BRIL, PAUL** (1554-1626), Flemish painter, born at Antwerp. On the death of his brother Matthew (1550-84), Paul succeeded to his pensions and employments at the Vatican. He painted landscapes with a depth of chiaroscuro then little practised in Italy, and introduced into them figures well drawn and finely coloured. One of his best compositions is the "Martyrdom of St. Clement," in the Sala Clementina of the Vatican.

**BRILL** (*Psetta laevis*), a flatfish closely related to the turbot, differing from it in having very small scales and no bony tubercles in the skin. It abounds on parts of the British coast, and is only less favoured for the table than the turbot itself.

**BRILLAT-SAVARIN, ANTHELME** (1755-1826), French gastronomist, was born at Belley, France, on April 1, 1755, and died in Paris on Feb. 2, 1826. In 1789 he was a deputy, in 1793 mayor of Belley. To escape proscription he fled from France to Switzerland, and thence to the United States. On the fall of Robespierre he returned to France, and in 1797 became a member of the court of cassation. He wrote various volumes on political economy and law, but his name is famous for his *Physiologie du goût* (1825) a witty compendium of the art of dining, of which a translation, *The Physiology of Taste*, was published, with introduction by Arthur Machen, in 1925.

**BRIMSTONE**, the popular name of sulphur (*q.v.*) particularly of the commercial "roll sulphur." The word means literally "burning stone"; the first part being formed from the stem of the Mid. Eng. *brennen*, to burn. Earlier forms of the word are *brystone*, *bernstone*, *brynstone*, etc.

**BRIN, BENEDETTO** (1833-1898), Italian naval administrator, was born at Turin on May 17, 1833, and became a naval engineer. In 1873 Admiral Saint-Bon, minister of marine, appointed him under-secretary of State. The two supplemented each other; Saint-Bon conceived a type of ship, Brin made the plans and directed its construction. On the advent of the Left to power in 1876, Brin was appointed minister of marine by Depretis. Then Italian naval industry, almost non-existent in 1873, made rapid progress. In his eleven years' ministry (1876-78 with Depretis, 1884-91 with Depretis and Crispi, 1896-98 with Rudini), he succeeded in creating large private ship-yards, engine works and metallurgical works for the production of armour, steel plates and guns. In 1892 he entered the Giolitti cabinet as minister for foreign affairs. He was minister of marine in the Rudini cabinet when he died, on May 24, 1898. He, more than any other man, must be regarded as the practical creator of the Italian navy.

**BRINDABAN**, a town of British India, in the Muttra district of the United Provinces, on the right bank of the Jumna, 6 m. N. of Muttra. Pop. (1921) 14,632. Brindaban is one of the most popular places of pilgrimage in India, being one of the group of Vaishnavite holy places, associated with the cult of Krishna as a youthful shepherd. It contains bathing-stairs, tanks and wells, and a great number of handsome temples, of which the finest is that of Govind Deva, a cruciform vaulted building of red sandstone, dating from 1590. The river is unfortunately shifting away from the town and leaving the bathing-ghats high and dry.

**BRINDISI** (anc. *Brundisium*, *q.v.*), archiepiscopal see, Apulia, Italy, province of Lecce, 24m. N.W. by rail from Lecce, and 346m. from Ancona. Pop. (1921), 31,073 (town); 35,335 (commune). The sheltered inner harbour, 30ft. and more in depth, allows ocean steamers to lie at the quays.

The castle of Frederick II. with huge round towers, guarded the inner harbour. The cathedral, ruined by earthquakes, was restored in 1743-49, but has some remains of its mosaic pavement (1178). The baptismal church of S. Giovanni al Sepolcro (11th century) is now a museum. S. Benedetto (1080) is another interesting church. The town was destroyed in 836 by Saracens,

but rebuilt (11th century) by Lupus the protospatharius or Byzantine governor. In 1071 it fell into the hands of the Normans, and it frequently appears in the history of the Crusades. Early in the 14th century the inner port was blocked by Giovanni Orsini, prince of Taranto; the town was devastated by pestilence in 1348, plundered in 1352 and 1383; but even greater damage was done by the earthquake of 1456. It was an important naval base in 1915-18, when the harbour was considerably deepened.

**BRINDISI**, a drinking song, the name being derived from the Italian *brindisi*, a toast.

**BRINDLEY, JAMES** (1716-1772), English engineer, was born at Thornsett, Derbyshire. He was apprenticed to a millwright near Macclesfield, and set up as a wheelwright at Leek. In 1752 he designed and set up an engine for draining some coal-pits at Clifton in Lancashire. Three years later he extended his reputation by completing the machinery for a silk-mill at Congleton. In 1759, when the duke of Bridgewater was anxious to improve the outlets for the coal on his estates, Brindley advised the construction of a canal from Worsley to Manchester. The difficulties in the way were great, but all were surmounted by his genius, and his crowning triumph was the construction of an aqueduct to carry the canal at an elevation of 39ft. over the river Irwell at Barton. The great success of this canal encouraged similar projects, and Brindley was soon engaged in extending his first work to the Mersey, at Runcorn. He then designed and nearly completed what he called the Grand Trunk Canal, connecting the Trent and Humber with the Mersey. The Staffordshire and Worcestershire, the Oxford and the Chesterfield canals were also planned by him, and altogether he laid out over 360m. of canals. He died at Turnhurst, Staffordshire, on Sept. 30, 1772. Brindley retained to the last a peculiar roughness of character and demeanour; he remained practically illiterate all his life, working without written calculations or drawings.

**BRINTON, DANIEL GARRISON** (1837-1899), American archaeologist and ethnologist, was born at Thornbury, Pa., on May 13, 1837. He graduated at Yale in 1858, studied for two years in the Jefferson Medical college, and for one year in Paris and Heidelberg. From 1862 to 1865, during the Civil War in America, he was a surgeon in the Union army, acting for one year, 1864-65, as surgeon in charge of the U.S. army general hospital at Quincy, Ill. After the war he practised medicine at Westchester, Pa., for several years; was the editor of a weekly periodical, the *Medical and Surgical Reporter*, in Philadelphia, from 1874 to 1887; became professor of ethnology and archaeology in the Academy of Natural Sciences in Philadelphia in 1884, and was professor of American linguistics and archaeology in the University of Pennsylvania from 1886 until his death at Philadelphia on July 31, 1899. He was president at different times of the Numismatic and Antiquarian Society of Philadelphia, of the American Folk-Lore Society and of the American Association for the Advancement of Science.

His principal works are:—*The Myths of the New World* (1868), the first attempt to analyse and correlate, according to true scientific principles, the mythology of the American Indians; *The Religious Sentiment: Its Sources and Aim: A Contribution to the Science and Philosophy of Religion* (1876); *American Hero Myths* (1882); *Essays of an Americanist* (1890); *Races and Peoples* (1890); *The American Race* (1891); *The Pursuit of Happiness* (1893); and *Religions of Primitive People* (1897). In addition, he edited and published a *Library of American Aboriginal Literature* (8 vols., 1882-90). See "The Brinton Memorial Meeting," *American Philos. Society Proceedings* (vol. 1, p. 210, 1900), which contains a complete bibliography.

**BRINVILLIERS, MARIE MADELEINE MARQUERITE D'AUBRAY**, MARQUISE DE (*c.* 1630-1676), French poisoner, daughter of Dreux d'Aubray, civil lieutenant of Paris, was born in Paris about 1630. In 1651 she married the marquis de Brinvilliers, then serving in the regiment of Normandy. Contemporary evidence describes her at this time as a pretty and much-courted little woman, with a fascinating air of child-like innocence. In 1659 her husband introduced her to his friend Godin de Sainte-Croix, whose mistress she became. Her father then secured the arrest of Sainte-Croix on a *lettre de cachet*. When Sainte-Croix left the Bastille he plotted with his willing mistress his revenge upon her father. She undertook to experiment with

the poisons which Sainte-Croix, possibly with the help of a chemist, Christopher Glaser, prepared, and found subjects ready to hand in the poor who sought her charity and the sick whom she visited in the hospitals. Meanwhile Sainte-Croix determined that not only M. Dreux d'Aubray but also the latter's two sons and other daughter should be poisoned, so that the marquise and himself might come into possession of the family fortune. In Feb. 1666, the marquise poisoned her father, and in 1670, with the connivance of their valet La Chaussée, her two brothers. Before any attempt could be made on the life of Mlle. Thérèse d'Aubray, Sainte-Croix died suddenly (1672), his glass mask having fallen off while he was preparing his poisons. The police were called in, and discovered among his belongings documents incriminating the marquise and La Chaussée. The latter was arrested, tortured into a complete confession, and broken alive on the wheel (1673), but the marquise took refuge in a convent at Liège, whence she was decoyed by a police emissary disguised as a priest. A full account of her life and crimes was found among her papers. She was taken to Paris, tortured and beheaded, and her body burned on July 16, 1676.

See Toiseleur, *Trois énigmes historiques* (1882); G. Roulier, *La Marquise de Brinvilliers* (1883); H. Stokes, *Madame de Brinvilliers and her Times* (1912, 2nd ed., 1924).

**BRIONI**, a group of islands north-west of Pola, separated from the west coast of Istria by the Strait of Fasana. The largest island, Brioni Maggiore, previously barren, has been converted into a favourite resort with large hotels, being supplied with water by an underground channel from the mainland. The vegetation is now almost tropical. A fine and very large Roman villa has been found on the beautiful bay of Val Catena, on the south of the island.

**BRIOSCO, ANDREA** (c. 1470-1532), Italian sculptor and architect, known as Riccio ("curly-headed"), was born at Padua. He is known by the church of Sta Giustina in Padua, but he is most famous as a worker in metal. His masterpieces are the bronze Paschal candelabrum (11ft. high) in the choir of the Santo (S. Antonio) at Padua (1515), and the two bronze reliefs (1507) of "David dancing before the Ark" and "Judith and Holofernes" in the same church. His bronze and marble tomb of the physician Girolamo della Torre in San Fermo at Verona was beautifully decorated with reliefs, which are now in the Louvre.

**BRIOUDE**, town of France, capital of an arrondissement in the department of Haute-Loire, on the left bank of the Allier, 47m. N.W. of Le Puy on the P.L.M. railway. Pop. (1926) 4,502. Brioude (anc. Brivas) was in turn captured by Goths (532), Burgundians, Saracens (732) and Normans. After 1361 the town was the headquarters of Bérenger, lord of Castelnau, who was leader of one of the bands of military adventurers which then devastated France. The knights (or canons) of St. Julian bore the title of counts of Brioude. The town has to a great extent escaped modernization, and its streets are narrow and irregular. The church of St. Julian (12th and 13th centuries) is in the Romanesque style of Auvergne, of which the choir, with its apse and radiating chapels and the mosaic ornamentation of the exterior, is a fine example. The plain in which it is situated is of great fertility; trade in grain, wood and wine is considerable, and market-gardening is carried on in the outskirts. Brioude is the seat of a sub-prefect, and of tribunals of first instance and of commerce.

**BRIQUETTING**. When coal is hewn and transported, much of it is unavoidably reduced to small pieces and dust, the supply of which frequently exceeds the demand. The material tends to accumulate, a loss to the coal mining industry and an obstacle to its further development. One of the most effective methods of overcoming this difficulty is a process in which the small coal is mixed with some binding material, such as pitch, and then compressed into blocks or briquettes (also known as "patent fuel") of various convenient shapes and sizes. Some ingenious householder probably first arrived at this particular solution, mixing his excess of small coal with clay and moulding it by hand into balls; a process which has been in vogue in various parts of the world for many years. But commercial briquettes must possess

clearly defined properties, which are lacking when made with inorganic binders like clay. They should be relatively free from ash and clinker-forming ingredients, water-proof, and sufficiently hard to stand transportation with a minimum of breakage. They should not crumble unduly during combustion, and the binder must not be too expensive.

Many materials have been tried; inorganic substances such as Portland cement, silicate of soda, lime and clay; and organic, such as resin, pitch, molasses, mucilage and starch. None of these so nearly approaches the ideal binder as "medium-soft coal-tar pitch," itself a by-product of coal when the latter is carbonized or baked in closed retorts or ovens. The pitch and various coals are blended in proportions depending on the purpose for which the fuel is intended. A good fuel for domestic use, yielding a high degree of radiant heat, can be made from a mixture of 80% anthracite, 11% bituminous coal, and 9% pitch. For steam-raising purposes a long flame is required, which cannot be obtained from anthracite. Steam coal therefore forms the chief ingredient; standard practice approximating to 65% steam coal, 10% bituminous coal, 16% anthracite, and 9% pitch. The price of pitch makes it imperative to use as little as possible consistent with adequate cohesion. In both types of fuel the pitch burns off rapidly, bringing the coking effect of the bituminous coal into play, thus keeping the briquetted material coherent long after the pitch itself has been consumed.

*Making the Blocks*.—The actual processes of manufacture are simple. The coal is washed to reduce the ash content, then dried, after which both coal and pitch are ground to a powder and fed by conveyors to a closed vessel known as a pug-mill or kneader. Here the materials are thoroughly mixed by means of rotating blades. Superheated steam is also admitted to the vessel, melting the pitch and reducing the mixture to a plastic mass. Domestic briquettes are most frequently egg-shaped, known as "ovooids" or "boulets," and are produced by passing the plastic material between rolls having semi-ovoid recesses in their faces. Into these recesses the material is compressed, emerging as briquettes weighing, in general, from one to one and a half ounces. Steam-raising briquettes are usually rectangular in shape, made in blocks weighing from 10 to 28lbs. The mixture falls into suitable moulds or recesses in a rotating table, the motion of which is intermittent. During each pause a stamp is forced into one of the moulds, compressing the material to the required shape and size.

The briquetting of lignite or brown coal, as practised in Germany and elsewhere, follows somewhat different lines. Lignite does not usually require any binder other than that contained within itself in the form of bitumen and water. Again, lignite may contain as much as 60% water, necessitating much more elaborate drying equipment. Owing to the highly inflammable and explosive nature of dry lignite dust it is essential that steam dryers only should be used.

Briquette manufacture originated in Germany, but has since been developed in many countries, among which may be mentioned Great Britain (South Wales), France, Belgium, Australia, the United States and Canada. The increasing demand for pitch for road surfacing and other purposes has reacted unfavourably on the black coal briquetting industry.

**BIBLIOGRAPHY**.—Literature on the subject is scanty. Reference may be made to vol. i. of Franke's *Handbook of Briquetting* (London); and Stillman's *Briquetting* (New York, 1923). Much information lies buried in the proceedings and publications of various British, European and American engineering and research societies and institutions. (H. P. V.)

**BRISBANE, ARTHUR** (1864- ), American newspaper editor, was born in Buffalo, N.Y., Dec. 12, 1864. After an education in the American public schools and five years spent in France and Germany, he entered the employ of the New York *Sun* in 1882 or 1883 as a reporter, later becoming its London correspondent and subsequently editor of the *Evening Sun*. From 1890 to 1897 he was connected with the New York *World*, as managing editor of different editions, and from 1897 to 1921 he was editor of the New York *Evening Journal*. He purchased the *Washington Times* of Washington (D.C.), in 1917, and the *Evening Wisconsin* of Milwaukee (Wis.), in 1918, selling both papers

to William Randolph Hearst in 1919. After 1918 he was editor of the Chicago *Herald* and *Examiner*. His editorials, which for more than two decades appeared in all the newspapers owned by W. R. Hearst, obtained for Mr. Brisbane a national reputation.

Among his publications are *Editorials from the Hearst Newspapers* (1906); *Mary Baker G. Eddy* (1908); and *To-day and the Future Day* (1925).

**BRISBANE, SIR THOMAS MAKDOUGALL** (1773-1860), Scottish soldier and astronomer, was born on July 23 1773, at Brisbane House, near Largs, in Ayrshire. He entered the army in 1789, and served in Flanders, the West Indies and the Peninsula. In 1814 he was sent to North America; on the return of Napoleon from Elba he was recalled, but did not arrive in time to take part in the battle of Waterloo. In 1821 he was appointed governor of New South Wales. During his four years of office, although he allowed the finances of the colony to get into confusion, he endeavoured to improve its condition by introducing the vine, sugar-cane and tobacco plant, and by encouraging the breeding of horses and the reclamation of land. At his instigation exploring parties were sent out, and one of these discovered the Brisbane river which was named after him. He established an astronomical observatory at Paramatta in 1822, and the *Brisbane Catalogue*, which was printed in 1835 and contained 7,385 stars, was the result of observations made there in 1822-26. The observatory was discontinued in 1855. After his return to Scotland he resided chiefly at Makerstoun in Roxburghshire, where he had a well-equipped observatory. Important magnetic observations were begun at Makerstoun in 1841, and the results gained him in 1848 the Keith prize of the Royal Society of Edinburgh, in whose *Transactions* they were published. In 1836 he was made a baronet, and G.C.B. in 1837; and in 1841 he became general. In 1833, he was elected president of the Royal Society of Edinburgh, after the death of Sir Walter Scott. He died at Brisbane House on Jan. 27 1860.

**BRISBANE**, the capital city of Queensland, Australia, situated (27° 28' S., 153° 2' E.) near the south-eastern corner of the state on the Brisbane River about 14m. from its mouth in Moreton Bay. The city lies astride the river, which here winds through gently hilly country; the low-lying river flats have been visited by disastrous floods. Inland the roomy basins and valleys of the Brisbane and Logan give access to the uplands of the Darling Downs and of northern New South Wales.

Northwards lowlands, interrupted by hill-ranges (Glasshouse Mountains), lead towards the central coastal basins. The climate is sub-tropical: mean ann. temps. about 78°-60° F (absol. extremes: 109°-36° F) with about 2,640 hours sunshine; av. ann. rainfall 45 in. (variation 88 in.-24 in.), falling chiefly in Dec.-March. Spells of excessive heat are very rare, but the heat for two or three months in summer is moist and oppressive. Brisbane began (1824) as a penal settlement, and was named after the Governor, Sir T. M. Brisbane. Its civil status was established in 1842, and, after a period of difficulties, it became (1859) the official capital of the newly-created colony of Queensland. The present metropolitan area (Greater Brisbane) covers some 10 sq.m. (including South Brisbane), and has a population of about 274,500 (1927) or about 31% of the total population of Queensland (birth-rate; about 23 deaths: about 10 per 1,000). Like the other Australian capitals, Brisbane is spacious, solidly built and well laid-out. There are also ample and beautiful recreation grounds, parks and public gardens. The city is served with electricity, has an abundant water supply and good sanitation. The river is crossed by bridges and services of ferry-boats. The centre of a rich agricultural, pastoral and mining area, stretching back to the Darling Downs and the western plains beyond, Brisbane has attracted to itself considerable trade and manufacturing industry. There were (1925) some 677 factories in all, employing 23,000 hands, and having a total output valued at nearly £17,225,000, (gross). The industries are connected mainly with the production of foodstuffs and clothing, but include also engineering, saw-milling, tanning and motor-building. Coal is conveyed downstream from Ipswich. Railways radiate inland in various directions, and link the Darling Downs (Warwick, Toowoomba, etc.)

to the capital, while the Charleville line, in particular, opens up the heart of pastoral Southern Queensland. Northwards the coastal line links the "sugar" ports and southwards main-line connection exists with Sydney (via Warwick), while a new (4' 8½" standard gauge) through-link is being constructed by the coastal route (South Brisbane-Kyogle). A dredged channel in the lower Brisbane river (400 ft. wide, 26-24 ft. deep low water with 7 ft.

BRISBANE, AUSTRALIA, SHOWING BRISBANE RIVER FROM PETRIE BIGHT, THE CUSTOMS HOUSE AND PART OF THE CIRCULAR QUAY

[max.] tidal rise) gives access to Brisbane from the sea. There are over 14,000 ft. of wharfage with depths alongside of 23-30 ft.; a proposed basin at Hamilton (about 4m. downstream) will provide a further 18,000 ft.; there is also a dry dock, and three patent slip ways. In 1925-26 over 3,000,000 tons of shipping used the port, including ships of the regular ocean lines. The total trade is valued at about £29,500,000, of which £18,000,000 represents exports (wool, meat, and other cattle products, sugar, dairy products, and maize, wool representing more than half of the total value). In spite of the extended nature of the coast and the relatively uncentralized nature of economic development in Queensland, Brisbane is by far the largest and most rapidly growing port.

**BRISEUX, CHARLES ÉTIENNE** (c. 1680-1754), French architect. He was especially successful as a designer of internal decorations—mantel-pieces, mirrors, doors and overdoors, ceilings, consoles, candelabra, wall panellings and other fittings, chiefly in the Louis Quinze mode. He also wrote on architectural subjects.

**BRISSAC, DUKES OF.** The fief of Brissac in Anjou was acquired at the end of the 15th century by a noble French family named Cossé belonging to the same province. Brissac was made a countship in 1560 for Charles de Cossé, who was grand master of artillery and governor of Piedmont and of Picardy. The second Charles de Cossé fought for the League and as governor of Paris opened the gates of that town to Henry IV., who created him marshal of France in 1594. Brissac was raised to a duchy in the peerage of France in 1611. Louis Hercule Timoléon de Cossé, duc de Brissac and commandant of the constitutional guard of Louis XVI., was killed at Versailles on Sept. 9, 1792.

**BRISSON, EUGÈNE HENRI** (1835-1912), French statesman, was born at Bourges on July 31, 1835, and died in April 1912. He was elected to the Assembly on Feb. 8, 1871, as a member of the extreme Left. He was the first to propose amnesty for the condemned Communards (Sept. 13, 1871), but the proposal was voted down. He strongly supported obligatory primary education and was a firm anti-clerical. He was president of the chamber from 1881—replacing Gambetta—to March 1885, when he became prime minister upon the resignation of Jules Ferry; but he resigned when, after the general elections of that year, he only just obtained a majority for the vote of credit for the Tongking expedition. He took a prominent part in exposing the

Panama scandals, was a powerful candidate for the presidency after the murder of President Carnot in 1894, and was again president of the chamber from December 1894 to 1898. In June of the latter year he formed a cabinet, when the country was violently excited over the Dreyfus affair; his firmness and honesty increased the respect in which he was already held by good citizens, but a chance vote overthrew his ministry in October. He actively supported the ministries of Waldeck-Rousseau and Combes, especially concerning the laws on the religious orders and the separation of Church and State. In 1899 he was a candidate for the presidency. In May 1906 he was elected president of the Chamber of Deputies and re-elected in 1912.

**BRISSON, MATHURIN JACQUES** (1723-1806), French zoologist and natural philosopher, was born at Fontenay le Comte on April 30, 1723. The earlier part of his life was spent in the pursuit of natural history, but after the death of R. A. F. Réaumur (1683-1757), whose assistant he was, he abandoned natural history, and was appointed professor of physics in Paris. His most important works were *Poids spécifiques des corps* (1787) and *Dictionnaire raisonné de physique* (2nd ed. 1800). He died at Croissy near Paris, on June 23, 1806.

**BRISOT, JACQUES PIERRE** (1754-1793), who assumed the name of DE WARVILLE, French Girondist, was born at Chartres, where his father was an innkeeper, on Jan. 14, 1754. Brisot received a good education and entered the office of a lawyer at Paris. His first works, *Théorie des lois criminelles* (1781) and *Bibliothèque philosophique du législateur* (1782), were on the philosophy of law, and showed how thoroughly Brisot was imbued with the ethical precepts of Rousseau. The first work was dedicated to Voltaire. Brisot was a prolific journalist and pamphleteer, and on an enforced absence from France he met some of the English abolitionists and visited the United States in 1788 in connection with the abolitionist movement.

From the first, Brisot threw himself heart and soul into the Revolution. He edited the *Patriote français* from 1789 to 1793, and being a well-informed and capable man took a prominent part in affairs. Upon the demolition of the Bastille the keys were presented to him. Famous for his speeches at the Jacobin club, he was elected a member of the municipality of Paris, then of the legislative assembly, and later of the national convention. During the legislative assembly his knowledge of foreign affairs enabled him as member of the diplomatic committee practically to direct the foreign policy of France, and the declaration of war against the emperor on April 20, 1792, and that against England on July 1, 1793, were largely due to him. While to others these were a crusade for liberty, to Brisot they were a convenient way of exposing and dethroning the king. He was inferior in many ways to the nobler Girondins like Vergniaud, but he was immensely their superior in parliamentary intrigue and political manoeuvring. So much did he become their leader that they were often named "Brisotins," and contemporary opinion often ascribed the violence of the conflict to the personal hatred between Robespierre and Brisot. He was involved in the downfall of his party and perished courageously by the guillotine on Oct. 31, 1793.

See Helena Williams, *Souvenirs de la Révolution française* (1827); *Mémoires de Brisot, sur ses contemporains et la Révolution française*, published by his sons, with notes by F. de Montrol (1830); F. A. Aulard, *Les Portraits littéraires à la fin du XVIII<sup>e</sup> siècle, pendant la Révolution* (1883); F. A. Aulard, *Les Orateurs de la Législative et de la Convention* (2nd ed. 1905).

**BRISTLES.** The strong, resilient hairs of the pig have become a very important article of commerce and are largely produced or imported by the great industrial nations. They are a chief raw material of the brush manufacture. The United Kingdom imports from 2,000 to 3,000 tons a year, valued at £1,100,000 to £2,000,000, and has a considerable re-export trade in them. In 1926 the British imports were 2,011 tons, valued (c.i.f.) at £1,077,000.

**BRISTOL, EARLS AND MARQUISES OF.** This English title has been held in the Hervey family since 1714, though previously an earldom of Bristol, in the Digby family, is associated with two especially famous representatives, of whom separate

biographies are given. The Herveys are mentioned during the 13th century as seated in Bedfordshire, and afterwards in Suffolk, where they have held the estate of Ickworth since the 15th century. John Hervey (1616-79), eldest son of Sir William Hervey (died 1660), was treasurer to Catherine, wife of Charles II. He left no children, and his estates passed to his brother, Sir Thomas Hervey, (died 1694).

His son JOHN HERVEY, 1st earl of Bristol (1665-1751) was educated at Clare Hall, Cambridge, and became member of parliament for Bury St. Edmunds in March 1694. In March 1703 he was created Baron Hervey of Ickworth, and in Oct. 1714 earl of Bristol. By his first wife, he had only one son, Carr, Lord Hervey (1691-1723), who was educated at Clare Hall, Cambridge, and was member for Bury St. Edmunds from 1713 to 1722. (It has been suggested that Carr, who died unmarried on Nov. 14, 1723, was the father of Horace Walpole.) He married secondly Elizabeth Felton, of Playford, Suffolk. His eldest son, John (1696-1743), gained some renown as a writer and a politician (see HERVEY OF ICKWORTH). Another son, Thomas (1699-1775), was one of the members for Bury from 1733 to 1747 and held various offices at court. A third son, Felton (1712-73), was also member of the family borough of Bury St. Edmunds. Having assumed the additional name of Bathurst, Felton's grandson, Felton Elwell Hervey-Bathurst (1782-1819), was created a baronet in 1818, and on his death a year later the title descended to his brother, Frederick Anne (1783-1824), the direct ancestor of the present baronet. The 1st earl died in Jan. 1751, the title and estates descending to his grandson.

GEORGE WILLIAM HERVEY, 2nd earl of Bristol (1721-1775), the eldest son of John, Lord Hervey of Ickworth, by his marriage with Mary (1700-68), daughter of Nicholas Lepell, was born on Aug. 31 1721. He served for some years in the army, and in 1755 was sent to Turin as envoy extraordinary. He was ambassador at Madrid from 1758 to 1761, and ranked among the followers of Pitt. Appointed lord-lieutenant of Ireland in 1766, he never visited that country during his short tenure of this office, and, after having served for a short time as keeper of the privy seal, became groom of the stole to George III. in Jan. 1770. He died unmarried in March 1775, and was succeeded by his brother.

AUGUSTUS JOHN HERVEY, 3rd earl of Bristol (1724-1779), entered the navy, served under Byng in the Mediterranean, and gave evidence at his trial in 1757. He was of great assistance to Admiral Hawke in 1759. Having served with distinction in the West Indies under Rodney, his active life at sea ceased when the Peace of Paris was concluded in Feb. 1763. Hervey was member of parliament for Bury from 1757 with a short interval, until he succeeded his brother in the peerage in 1775. Having served as a lord of the admiralty from 1771 to 1775 he won some notoriety as an opponent of the Rockingham ministry and a defender of Admiral Keppel. In Aug. 1744 he had been secretly married to Elizabeth Chudleigh (1720-88), afterwards duchess of Kingston (q.v.), but this union was dissolved in 1769. The earl died in London on Dec. 23, 1779, leaving no legitimate issue, and having, as far as possible, alienated his property from the title. He was succeeded by his brother. Many of his letters are in the Record Office, and his journals in the British Museum. Other letters are printed in the *Grenville Papers*, vols. iii. and iv. (London, 1852-53), and the *Life of Admiral Keppel*, by the Hon. T. Keppel (London, 1852.)

FREDERICK AUGUSTUS HERVEY, bishop of Derry (1730-1803), 4th earl of Bristol, was educated at Westminster school and Corpus Christi college, Cambridge, graduating in 1754. Entering the church he became a royal chaplain. In Feb. 1767, he was made bishop of Cloyne, and a year later of Derry. In Dec. 1779 he became earl of Bristol. In 1782 he threw himself ardently into the Irish volunteer movement. His later years were spent mainly on the continent. In 1798 he was imprisoned by the French at Milan, remaining in custody for 18 months. He died at Albano on July 8 1803, and was buried in Ickworth church. In 1752 he had married Elizabeth (d. 1800), daughter of Sir Jermyn Davers, Bart., by whom he had two sons and three daughters. His elder son, Augustus John, Lord Hervey (1757-96), had pre-deceased his father, and he was succeeded in the title by his younger son.

FREDERICK WILLIAM HERVEY, 5th earl and 1st marquis of Bristol (1769–1859), was born on Oct. 2, 1769, and died Feb. 15, 1859. He married Elizabeth Albana (d. 1844), daughter of Clotworthy, 1st Baron Templetown, by whom he had six sons and three daughters. In 1826 he was created marquis of Bristol and Earl Jermyn. He was succeeded by his son Frederick William (1800–64), M.P. for Bury St. Edmunds 1830–59, as 2nd marquis; and by the latter's son Frederick William John (1834–1907), M.P. for West Suffolk 1859–64, as 3rd marquis. The latter's nephew, Frederick William Fane Hervey (born 1863), who succeeded as 4th marquis, served with distinction in the royal navy; and was M.P. for Bury St. Edmunds from 1906 to 1907.

**BIBLIOGRAPHY.**—See John, Lord Hervey, *Memoirs of the Reign of George II.*, edited by J. W. Croker (1884); John Hervey, 1st earl of Bristol, *Diary* (Wells, 1894); and *Letter Books of Bristol; with Sir T. Hervey's Letters during Courtship and Poems during Widowhood* (Wells, 1894). Also the articles in the *Dictionary of National Biography*, vol. xxvi. (1891).

**BRISTOL, GEORGE DIGBY, 2ND EARL OF (1612–1677)**, eldest son of John Digby, 1st earl (*see below*), was born in Oct. 1612. He entered Magdalen college, Oxford, in 1626, and after taking his M.A. degree in 1636, travelled abroad for some years. In 1638–39 he attacked Roman Catholicism in a series of letters to Sir Kenelm Digby. Elected member for Dorsetshire he supported Pym and Hampden in the parliaments of 1640, and was one of the committee for the impeachment of Strafford. But in 1641 he voted against the third Attainder bill, and defended episcopacy in the debates on the Root and Branch bill. To save him from the attacks of the Commons, the king raised him to the peerage, in his father's barony of Digby, and he became one of Charles's advisers. He urged on the arrest of the five members in Jan. 1642, and was soon after forced to escape impeachment by flying to Holland. From there he wrote letters discussing plans to win Dutch support, which were intercepted on their way to Charles. Digby fought at Edgehill, but threw down his commission in consequence of a quarrel with Prince Rupert. In 1643 he was made secretary of state and privy councillor, and in Oct. 1645 lieutenant general of the king's forces north of the Trent. On Oct. 15 he was defeated at Sherburn, his correspondence disclosing royal intrigues with Ireland and Scotland was captured and he was forced to escape to the Isle of Man and finally to France where he served in Louis XIV.'s troops in the Fronde. In 1656 Mazarin, who regarded Digby as a mere adventurer, had him expelled from France in accordance with the treaty with Cromwell, and he joined Charles II. at Bruges. Charles appointed him secretary of state in 1657, but on his becoming a Roman Catholic he had to resign office.

By the death of his father Digby succeeded, in 1659, to the peerage as 2nd earl of Bristol. He returned to England at the Restoration, but was excluded from office on account of his religion. He adopted an attitude of violent hostility to Clarendon, and on July 10 1663, brought forward a charge of high treason against him. The charge was dismissed, and Clarendon expelled from court. On the fall of Clarendon, however, Bristol was again welcomed at court, and took his seat in the Lords, July 29 1667. In March 1673, though still a Roman Catholic, he spoke in favour of the Test act, describing himself as a "Catholic of the Church of Rome, not a Catholic of the court of Rome." He died on March 20 1677.

Lister (1838); *State Papers*.

**BRISTOL, JOHN DIGBY, 1ST EARL OF (1580–1653)**, English diplomatist, son of Sir George Digby of Coleshill, Warwickshire, was educated at Magdalen college, Oxford, and entered the Inner Temple in 1598. Between 1611 and 1624 he was constantly employed as ambassador of James I., notably in the negotiations for the Spanish marriage. During a short interval in 1622 he was sent to Brussels and Vienna to advocate the cause of the king's son-in-law, the elector palatine. In 1623, when the

negotiations for the Spanish marriage were wrecked by the behaviour of Charles and Buckingham in Madrid, Digby incurred Buckingham's resentment by sending home an account of the true state of affairs. On his arrival at Dover in March 1624 he was forbidden to appear at court. On the death of James he was removed by Charles I. from the Privy Council, and ordered to absent himself from his first parliament. In March 1626, after the assembling of the second parliament, Digby applied to the Lords, who supported his rights, and Charles sent him his writ accompanied by a letter desiring him not to use it. Bristol, however, took his seat and demanded justice against Buckingham. The king endeavoured to obstruct his attack by causing Bristol, on May 1, to be himself brought to the bar, on an accusation of high treason by the attorney-general. The Lords, however, ordered that both charges should be investigated simultaneously. Further proceedings were stopped by the dissolution of parliament on June 15, a prosecution was ordered by Charles in the Star Chamber, and Bristol was sent to the Tower, where he remained till March 17, 1628, when the peers, on the assembling of Charles's third parliament, insisted on his liberation and restoration to his seat in the Lords.

In the discussions upon the Petition of Right, Bristol supported the use of the king's prerogative in emergencies, but joined in the demand for a full acceptance of the petition by the king after the first unsatisfactory answer. He was now restored to favour, but took no part in politics till the outbreak of the Scottish rebellion, when he warned Charles of the danger of attacking with inadequate forces. He was the leader in the Great Council held at York, was a commissioner to treat with the Scots in Sept. 1640 at Ripon, and advised strongly the summoning of the parliament. In Feb. 1641 he advocated reforms in the Administration and received a seat in the council. Though no friend to Strafford, he endeavoured to save his life, desiring only to see him excluded from office. On Dec. 27, he was declared an evil counsellor by the House of Commons, Cromwell on the 28th moving an address to the king to dismiss him from his councils, on the plea that he had advocated the bringing up of the northern army to overawe parliament in the preceding spring. There is no evidence to support the charge, but Digby was regarded by the parliamentary party with special hatred and distrust, of which the chief causes were probably his Spanish proclivities and his indifference on the great matter of religion. On March 28, 1642, he was sent to the Tower for having failed to disclose to parliament the Kentish petition. Liberated in April, he joined Charles at York, was present at Edgehill and accompanied him to Oxford. On Feb. 1, 1643, he was named with Lord Herbert of Raglan for removal from the court and public office for ever, and in the propositions of Nov. 1644 was one of those excepted from pardon. In January he had endeavoured to instigate a breach of the Independents with the Scots. Bristol, however, was not in favour of continuing the war, and withdrew to Sherborne, removing in the spring of 1644 to Exeter, and after the surrender of the city retiring abroad on July 11, by order of the Houses, passing the rest of his life in exile at Caen. In 1647 he printed *An Apology*, defending his support of the royal cause. This was reprinted in 1656 (Thomason Tracts, E. 897, 6). He died in Paris on Jan. 16, 1653, and was succeeded by his son, George, as 2nd earl. Besides his *Apology*, he was the author of several printed speeches and poems, and translated *A Defence of the Catholic Faith* by Peter du Moulin (1610).

**BRISTOL**, parliamentary and county borough, city and seaport of England, in Gloucestershire and Somersetshire, but also a separate county in itself with its own assizes, lying on both sides of

the river Avon at the confluence of the rivers Avon and Frome, 118m. W. of London by rail. Population (1921) 376,975; (census of 1931) 396,918. The Avon here forms the boundary between Gloucestershire and Somersetshire. Although entering the Bristol Channel only eight m. below the city, it is confined between considerable hills, with a narrow valley-floor on which the nucleus of the city rests. Between Bristol and the Channel the valley becomes a gorge, crossed by the famous Clifton Suspension bridge. Above Bristol the hills again close in at Keynsham, so that the city lies in a basin-like hollow some four m. in diameter, and extends up the heights to the north. The G.W.R., striking into the Avon valley near Bath, serves Bristol from London, connects it with South Wales by the Severn tunnel, and with the southern and south-west counties of England. The G.W.R. express trains to London, however, are run on the line via Badminton. Local lines of this company encircle the city on the north and south, serving the outports of Avonmouth and Portishead on the Bristol Channel. A trunk line of the L.M.S.R. connects Bristol with the north by way of Gloucester, Worcester, Birmingham and Derby. The central station, Temple Meads, is used by the G.W.R., and by the L.M.S. and L.N.E. Joint Railways.

**Early History.**—Bristol (Brigstow, Bristou, Bristole) is one of the best examples of a town that has owed its greatness entirely to trade. It was the western limit of the Saxon invasion of Britain, and about the year 1000 a Saxon settlement began to grow up at the junction of the rivers Frome and Avon. Bristol owed much to Danish rule, and during the reign of Canute, when the wool trade with Ireland began, it became the market for English slaves. In Domesday it was already a royal borough, with a mint. One-third of the gold was paid to Geoffrey de Coutances, bishop of Exeter, who threw up the earthworks of the castle. Earl Robert of Gloucester still further strengthened the castle, probably with masonry, and involved Bristol in the rebellion against Stephen. A charter of 1172 granted the city of Dublin to the men of Bristol as a colony with the same liberties as their own town.

As a result probably of the close connection between Bristol and Ireland the growth of the wool trade was maintained. About this time Bristol began to export wool to the Baltic, and had developed a wine trade with the south of France, while soap-making and tanning were flourishing industries. Bristol was still organized manorially rather than municipally.

At some date after this a commune was established in Bristol on the French model, Robert FitzNichol, the first mayor of Bristol, taking the oath in 1200. The mayor was chosen by the merchants of Bristol who were members of the merchant gild.

In the reign of John, Bristol began the struggle to absorb the neighbouring manor of Bedminster, the eastern half of which was held by the Templars by gift of Earl Robert of Gloucester, while the western half, known as Redcliffe, had been sold to Robert FitzHardinge. The Templars acquiesced, but the wealthy owners of Redcliffe resisted for nearly 100 years. In 1247 a new course was cut for the river Frome, vastly improving the harbour, and a stone bridge was built over the Avon, bringing Temple and Redcliffe into closer touch with the city. About this time Bristol seems to have become practically independent of the king. The exclusiveness of the merchant gild led to the insurrection of 1312. During the reign of Edward III., cloth manufacture developed in Bristol. Thomas Blanket set up looms in 1337, employing many foreign workmen, and in 1353 Bristol was made one of the staple towns.

The charter of 1373 extended the boundaries of the town to include Redcliffe (thus settling the long-standing dispute) and the waters of the Avon and Severn up to the Steep and Flat Holmes, and made Bristol a county in itself, independent of the county courts. It was the first city outside of London to receive this honour. This charter (confirmed in 1377 and 1488) was followed by the era of William Canyng, of the foundation of the Society of Merchant Venturers, and of the voyages of John and Sebastian Cabot. William Canyng (1399–1474) was five times mayor and twice represented Bristol in parliament; he carried on a large cloth trade with the Baltic and rebuilt St. Mary Redcliffe.

At the same time cloth was exported by Bristol merchants to France, Spain and the Levant. The records of the Society of Merchant Venturers began in 1467; by 1500 it directed all the foreign trade of the city and had a lease of the port dues. It was incorporated in 1552, and received other charters in 1638 and 1662.

In the 16th century Bristol traded with Spain, the Canaries and the Spanish colonies in America, shared in the attempt to colonize Newfoundland, and began the trade in African slaves which flourished during the 17th century. A formal charter of incorporation was granted in 1664. In the 18th century the cloth trade declined owing to the competition of Ireland and to general migration of manufactures to the northern coalfields, but prosperity was maintained by the introduction of manufactures of iron, brass, tin and copper, and by the flourishing West Indian trade, sugar being taken in exchange for African slaves.

The hot wells became fashionable in the reign of Anne (who granted a charter in 1710), and a little later Bristol was the centre of the Methodist revival of Whitfield and Wesley. The city was small, densely populated and dirty, with dark, narrow streets, and the mob gained notoriety for violence in the riots of 1708, 1753, 1767 and 1831. At the beginning of the 19th century prosperity was diminishing, comparatively if not actually, owing to (1) the rise of Liverpool, which had more natural facilities as a port than Bristol, (2) the abolition of the slave trade, which ruined the West Indian sugar trade, and (3) the extortionate rates levied by the Bristol Dock Company, incorporated in 1803. The decline was checked by the efforts of the Bristol chamber of commerce (founded in 1823) and by the Municipal Reform Act of 1835. The new corporation bought the docks in 1848 and reduced the fees.

**Modern Bristol.**—Bristol, with its proud traditions, retains a remarkable collection of picturesque buildings. The eccle-

CHURCH OF ST. MARY REDCLIFFE, BRISTOL, ONE OF THE MOST BEAUTIFULLY PROPORTIONED PARISH CHURCHES IN ENGLAND, BUILT IN THE 14TH CENTURY

siastical foundations are particularly noteworthy. This the city owes mainly to a few great baronial families, such as the earls of Gloucester and the Berkeleys, in its early history, and to the great merchants, Canyngs, Shipwards and Framptons, in its later career. The see of Bristol, founded by Henry VIII. in 1542, was united to that of Gloucester in 1836, but again separated in 1896. The diocese includes parts of Gloucestershire and Wiltshire, and a small but populous portion of Somerset. The cathedral is pleasantly situated on the south side of College Green. It was once the abbey of St. Augustine (1142) and there remain from Nor-

man times the entrance gateway, the abbots' gateway and the chapter-house; the last mentioned among the finest of Norman chambers in Europe. On the north side of College Green is the small but beautiful Gothic St. Mark's, or the Lord Mayor's chapel. This building, restored in 1888, was founded in 1285. The long Early English nave is peculiar in standing nearly due north and south. The chantry chapel of Sir Robert Poyntz, with its fan tracery roof, is a perfect example of Tudor architecture. The chapel was purchased by the Corporation from Henry VIII., and since 1722 has been devoted to the services of the Mayor and Corporation. Among conventual remains are the Dominican Priory, St. Bartholomew's Hospital, the small chapel of the Three Kings of Cologne, and Holy Trinity Hospital. The following churches are noteworthy:—St. Stephen's (15th century); St. John's (15th century); St. James's (1130), which has a Norman nave and a 14th-century tower; St. Mary le Port and St. Augustine the Less, which are perpendicular. On the island south of the Floating Harbour are two of the finest churches in the city. Temple church, with its leaning tower, is of the Decorated and Perpendicular periods. The church of St. Mary Redcliffe, for grandeur of proportion and elaboration of design and finish, is the first ecclesiastical building in Bristol, and takes high rank among the parish churches of England. It was built for the most part in the latter part of the 14th century by William Canyng or Canynges (*q.v.*), but retains Early English work. The fine tower is Decorated but the spire, Decorated in style, is modern. The church exhibits the rare feature of transeptal aisles. Of St. Thomas's in the vicinity, only the tower (15th century) remains of the old structures. All Hallows' church is, in the main, of the 15th century, and is interesting from its connection with the ancient gild of calenders, whose office it was "to convert Jews, instruct youths," and to keep the archives of the town. There was the first free library in the city, possibly in England. There are many good specimens of ancient domestic architecture—notably some arches of a grand Norman hall and some Tudor windows of Colston's house, Small street; and Canyng's house, with good Perpendicular oak roof. Among buildings to which historic interest attaches are the Merchant Venturers' almshouses (1699) adjoining their hall. St. Peter's hospital (adjoining St. Peter's church) is a gabled building mainly of Jacobean date, with a fine court-room and beautiful carved timber front. The public buildings are somewhat overshadowed in interest by the ecclesiastical. The council house, at the "Cross" of the four main thoroughfares, dates from 1827 and contains the city archives. The exchange (used as a corn market) is a noteworthy building by the famous architect of Bath, John Wood (1743). Edward Colston, citizen and benefactor of the city (d. 1721), is commemorated by name in several buildings and institutions, notably in Colston Hall (bought by the city in 1919), used for concerts and meetings. A bank close by St. Stephen's church claims to have originated in the first savings-bank established in England (1812). Similarly, the city free library (1613) is considered to be the original of its kind. An art gallery, presented by Sir William Henry Wills, was opened in 1905.

University College (1876) forms the nucleus of the University of Bristol (chartered 1909). The new buildings, designed by Sir George Oatley, and opened by King George in 1925, were the gift of Sir George Wills and Mr. H. H. Wills, as a memorial to their father, the first Chancellor of the university. The Grammar School (1532), opposite the main university buildings, was enlarged in 1914. Clifton College, a modern public school, was founded in 1862. There is a technical college of the Company of Merchant Venturers (1885), where the University Faculty of Engineering is housed. The medical charities of Bristol are considerable in number and of various origins.

Of the open spaces in and near Bristol the most extensive are those bordering the river in the neighbourhood of the gorge, Durdham and Clifton Downs, on the Gloucestershire side (*see CLIFTON*). Others are Victoria Park, south of the river; Eastville Park by the Frome, on the northeast of the city; St. Andrew's Park to the north; and Brandon Hill, west of the cathedral, an abrupt eminence commanding a fine view over the city, and

crowned with a modern tower commemorating the "fourth centenary of the discovery of America by John Cabot, and sons, Lewis, Sebastian and Sanctus." But, like other places with a long history, Bristol is faced with the problem of slums. It was stated in 1927 that at least 25,000 people were compelled to live, within the boundaries of the city, in houses which were unfit for occupation.

**The Harbour.**—Bristol harbour was formed in 1809 by the conversion of the Avon and a branch of the Frome into "the Float," by cutting a new channel for the Avon, and by the forma-

tion of two basins. Altogether, the water area, at fixed level, is about 85ac. Four dry docks open into the floating harbour. In 1884 the Avonmouth and Portishead docks at the river entrance (constructed in 1877–80) were bought up by the city, and the port extends from Hanham Mills on the Avon to the mouth of the river, and for some distance down the estuary of the Severn. The city docks have a depth of 22ft., while those at Avonmouth are accessible to the largest vessels. Revival of trade, rapid increase of population and enlargement of the city boundaries followed after 1884. In 1902 the construction of the extensive Royal Edward dock at Avonmouth was put in hand by the corporation, and the dock was opened by King Edward VII. in 1908. It is entered by a lock 875ft. long and

CABOT TOWER ERECTED ON BRANDON HILL, BRISTOL, IN COMMEMORATION OF JOHN CABOT AND HIS SONS

roof, wide, with a depth of water on the sill of 46ft. at ordinary spring and 36ft. at ordinary neap tides. The water area is about 44ac., the total area of the dock premises being 539ac. Grain storage accommodation is provided for by two silo granaries, and a third under construction in 1927 brings the total capacity to 62,000 tons. Notable features are the Royal Edward cold stores, the passenger station, graving dock and the ferro-concrete transit sheds. The eastern arm extension, under construction in 1927, provides six additional deep-water berths.

Portishead dock, on the Somerset shore, has an area of 14ac. The Port of Bristol, through Avonmouth and Portishead docks, has proved a most convenient centre for the distribution of petroleum and its products, received in bulk from large ocean tank-steamers. Avonmouth and Bristol are connected by the new "low-level road" which necessitated extensive blasting in the Avon Gorge. The port has a large trade with America, the West-Indies and elsewhere, the principal imports being grain, sugar, tobacco, metals, petroleum, fruit, oils, ore, timber, hides, cattle and general merchandise; while the exports include machinery, chemicals, hardware, manufactured oils, cotton goods, tin and salt. The Elder-Dempster, Dominion and other large steamship companies trade at the port.

The principal industries are ship-building, chocolate factories, sugar refineries, tobacco mills, glass works, potteries, soaperies, shoe factories, leather works and tanneries, chemical works, saw mills, breweries, iron works, machine works, stained-paper works, anchors, chain cables and sailcloth. A coal-field extending 16m. south-east to Radstock avails much for Bristol manufactures.

The parliamentary borough is divided into five divisions, each returning one member. The government of the city is in the hands of a lord mayor, 22 aldermen and 66 councillors. Area (1931) 19,674ac.

Harvey, *Bristol—an historical and topographical account of the city*; *The Official Guide to the City of Bristol* (1927), and W. Dodgson Bowman, *Bristol* (1927).

**BRISTOL**, an industrial city of Hartford county, Connecticut, U.S.A., in the central part of the State, 16m. S.W. of Hartford, on the Pequabuck river and served by the New York, New Haven and Hartford railroad. It is co-extensive with Bristol township and has an area of 27 sq. miles. The population in 1920 was 20,620, of whom 5,638 were foreign-born white; and was 28,451 in 1930 Federal census. Bristol has been noted for its clocks since the 18th century, and they are still one of its leading products. It has many other manufactures, including sheet brass and sheet steel and a great variety of steel and brass articles. The aggregate factory product in 1925 was valued at \$37,132,061. Tobacco is grown in the vicinity. Bristol was settled about 1727. Before and during the revolution it had a strong loyalist faction. The rector of the Protestant Episcopal church, the Rev. James Nichols, was tarred and feathered by the whigs; and Moses Dunbar, a member of the church, was hanged for treason. Chippen's Hill was a favorite rendezvous of the Loyalists, and a cave there is known as "the Tories' den."

**BRISTOL**, a borough of Bucks county (Pa.), U.S.A., on the Delaware river, opposite Burlington (N.J.), 20m. north-east of Philadelphia, and served by the Pennsylvania railroad. The population in 1920 was 10,273, of whom 2,453 were foreign-born white; and was 11,799 in 1930 Federal census. Its manufactures include carpets, worsted and woollen yarns, boilers and machinery, patent leather, soap, chemicals, towels, and aeroplanes. The factory product in 1925 was valued at \$8,485,303. Bristol was settled soon after William Penn received his charter in 1681, and until 1725 was the seat of government of the county. It was incorporated in 1720.

**BRISTOL**, the shire-town of Bristol county (R.I.), U.S.A., 15m. S.E. of Providence, on a peninsula between Narragansett bay and Mount Hope bay. It is served by the New York, New Haven and Hartford railroad, and by a ferry to the island of Rhode Island. The population in 1930 was 11,953 Federal census. The principal village, Bristol, has a deep and capacious harbour, which has little commerce, except for a few coal barges, but is used largely by yachts, and is headquarters for a fishing fleet of power boats. It is a renowned yacht building centre, and has large manufactures of rubber and woollen goods. The manufactured products in 1925 were valued at \$15,861,781. In the north-east part of the town is the Rhode Island Soldiers' Home (established 1890).

The town is part of the land awarded to Plymouth Colony in 1676, at the close of "King Philip's War." It was incorporated by the Colony in 1681, and named after Bristol, England, in anticipation of a commercial future. It became the shire-town in 1685; came under the jurisdiction of Massachusetts in 1692; and in 1747 was annexed to Rhode Island. The village was bombarded by the British, Oct. 7, 1775, and partially destroyed by a British force, May 25, 1778.

**BRISTOL**, an urban unit on the Tennessee-Virginia (United States) boundary line, formed of two adjoining cities, one in Sullivan county, Tenn., the other in Washington county, Virginia. The State line runs through the main business street, and each city is necessarily a distinct political unit, though in other respects they are practically a single community. They are on Federal highway 11 and are served by the Norfolk and Western and the Southern railways. The combined population in 1920 was 14,776 (8,047 in Tennessee, 6,729 in Virginia), of whom 2,001 were negroes; and in 1930, 20,845, in Tennessee 12,005, in Virginia 8,840.

Bristol is in the midst of beautiful mountain scenery, within 10m. of the Unaka National Forest. The city has an elevation of 1,760ft. and neighbouring peaks range from 3,800 to 5,000ft. above the sea. It is surrounded by vast timber resources and mineral deposits in four States. Coal comes from mines only 70m. away. It is a shipping point for tobacco, butter, cheese and iron, and has a variety of manufacturing industries (the greater part on the Virginia side) whose output in 1925 was valued at \$9,070,436. King college, a Presbyterian institution for men, is on the Tennessee side; Sullins college and Virginia Interment college, both for women, on the Virginia side. At Emory, Va., 25m. N.E., is Emory and Henry College, a co-educational institution founded by

the Methodist Episcopal Church South in 1836. Bristol, Va., was known as Goodson before its incorporation as a city in 1890. It has a city-manager form of government, and is administratively independent of Washington county.

**BRISTOW, BENJAMIN HELM** (1832-1896), American lawyer and politician, was born in Elkton, Ky., on June 20, 1832. He graduated at Jefferson college, Cannonsburg, Pa., in 1851, studied law under his father, and was admitted to the Kentucky bar in 1853. During the Civil War he was lieutenant colonel of the 25th Kentucky infantry and helped to recruit the 8th Kentucky cavalry, of which he became lieutenant colonel and later colonel. Thereafter he was successively State senator, assistant U.S. district attorney, district attorney for the Louisville district, and the (first appointed) solicitor general of the United States. As secretary of the Treasury (1874-76) he prosecuted with vigour the so-called "Whisky Ring," the headquarters of which was at St. Louis, and which, beginning in 1870 or 1871, had defrauded the Federal Government out of millions of dollars of its rightful revenue from the distillation of whisky. Distillers and revenue officers in various cities were implicated; and prominent among the ring's alleged accomplices at Washington was Orville E. Babcock, private secretary to President Grant, whose personal friendship for Babcock was unshaken by the evidences of the latter's guilt. Through Bristow's efforts more than 200 men were indicted, a number of whom were convicted, but after some months' imprisonment pardoned. Bristow, in the President's disfavour because of his public services, resigned his portfolio in June, 1876. As secretary of the Treasury he advocated a resumption of specie payments and at least a partial withdrawal of "greenbacks." A prominent candidate for the Republican presidential nomination in 1876, he gave his support to Hayes when his own nomination was seen to be impossible. After 1878 he practised law in New York city, where he died June 22, 1896.

**BIBLIOGRAPHY.**—*Whiskey Frauds*, 44th Cong., 1st Sess., Mis. Doc. No. 186; John McDonald, *Secrets of the Great Whiskey Ring* (1880); David Willcox, *Memorial of Benjamin Helm Bristow* (Cambridge, Mass., 1897); E. P. Oberholtzer, *Since the Civil War* (vol. iii., 1926).

**BRISTOW**, a city among the oil and gas wells of Creek county, Okla., United States, 65m. N.E. of Oklahoma city. It is on Federal highway 66, and is served by the Frisco lines and the Oklahoma-Southwestern railway. The population in 1920 was 3,460; in 1930 it was 6,619 by the Federal census. It is a supply point for the oil fields, and has oil refineries, cotton gins, cotton and cotton-seed oil mills, silica sand works, and glass factories. The county ginned 38,356 bales of cotton in 1926. Bristow was settled in 1901, incorporated as a town in 1902, and as a city of the first class in 1917.

**BRITAIN**, the anglicized form of the classical name of England, Wales and Scotland, sometimes extended to the British Isles as a whole (Gr. *Περαινακή νῆσος*, *Βερραιβία*; Lat. *Britannia*, rarely *Brittania*). The Greek and Roman forms are doubtless attempts to reproduce a Celtic original, the exact form of which is still a matter of dispute. Brittany (Fr. *Bretagne*) in western France derived its name from Britain owing to migrations in the 5th and 6th century A.D.

In what follows, the archaeological interest of early Britain is dealt with, in connection with the history of Britain in pre-Roman, Roman, and Anglo-Saxon days; this account being supplementary to the articles ENGLAND; ENGLISH HISTORY; SCOTLAND, etc.

#### PRE-ROMAN BRITAIN

Geologists are not yet agreed when and by whom Britain was first peopled. It used to be believed that the Palaeolithic men, who may or may not have been the earliest inhabitants, had died out or retired before their successors arrived. This view now requires modification in the light of the discovery of stray vestiges of "Mesolithic" cultures—Azilian, Tardenoisian, Maglemosian. During the Neolithic and Bronze ages we can dimly trace further immigrations. Real knowledge begins with two Celtic invasions, that of the Goidels in the later part of the Bronze age, and that of the Brythons and Belgae in the Iron age. These invaders brought Celtic civilization and dialects. It

is uncertain how far they were themselves Celtic in blood and how far they were numerous enough to absorb or obliterate the races which they found in Britain. But it is not unreasonable to think that they were no mere conquering caste, and that they were of the same race as the Celtic-speaking peoples of the western continent. By the age of Julius Caesar all the inhabitants of Britain, except perhaps some tribes of the far north, were Celts in speech and customs. Politically they were divided into separate and generally warring tribes, each under its own prince. They dwelt in hill forts with walls of earth or rude stone, or in villages of round huts sunk into the ground and resembling those found in parts of northern Gaul, or in subterranean chambered houses, or in hamlets of pile-dwellings constructed among the marshes. But, at least in the south, market centres had sprung up, town life was beginning, houses of a better type were perhaps coming into use, and the southern tribes employed a gold coinage and also a currency of iron bars or ingots, attested by Caesar and by surviving examples, which weigh roughly, some  $\frac{3}{4}$  lb., some  $2\frac{3}{4}$  lb., but mostly  $1\frac{1}{2}$  lb. In religion, the chief feature was the priesthood of Druids, who here, as in Gaul, practised magical arts and barbarous rites of human sacrifice, taught a secret lore, wielded great influence, but, at all events as Druids, took ordinarily no part in politics. In art, these tribes possessed a native Late Celtic fashion, descended from far-off Mediterranean antecedents and more directly connected with the La-Tène culture of the continental Celts. Its characteristics were a flamboyant and fantastic treatment of plant and animal (though not of human) forms, a free use of the geometrical device called the "returning spiral," and much skill in enamelling. Its finest products were in bronze, but the artistic impulse spread to humbler work in wood and pottery. The late Celtic age was one which genuinely delighted in beauty of form and detail. In this it resembled the middle ages rather than the Roman empire or the present day, and it resembled them all the more in that its love of beauty, like theirs, was mixed with a feeling for the fantastic and the grotesque. The Roman conquest of northern Gaul (57-50 B.C.) brought Britain into definite relation with the Mediterranean. It was already closely connected with Gaul, and when Roman civilization and its products invaded Gallia Belgica, they passed on easily to Britain. The British coinage now begins to bear Latin legends, and after Caesar's two raids (55, 54 B.C.) the southern tribes were regarded at Rome, though they do not seem to have regarded themselves, as vassals. Actual conquest was, however, delayed. Augustus planned it. But both he and his successor Tiberius realized that the greater need was to consolidate the existing empire, and absorb the vast additions recently made to it by Pompey, Caesar and Augustus.

### ROMAN BRITAIN

**I. The Roman Conquest.**—The conquest of Britain was undertaken by Claudius in A.D. 43. Two causes coincided to produce the step. On the one hand a forward policy then ruled at Rome, leading to annexations in various lands. On the other hand, a probably philo-Roman prince, Cunobelin (known to literature as Cymbeline), had just been succeeded by two sons, Caratacus (*q.v.*) and Togodumnus, who were hostile to Rome. Caligula, the half-insane predecessor of Claudius, had made in respect to this event some blunder which we know only through a sensational exaggeration, but which doubtless had to be retrieved. An immediate reason for action was the appeal of a fugitive British prince, presumably a Roman partisan and victim of Cunobelin's sons. So Aulus Plautius with a singularly well equipped army of some 40,000 men landed in Kent and advanced on London. Here Claudius himself appeared—the one reigning emperor of the 1st century who crossed the waves of ocean—and the army, crossing the Thames, moved forward through Essex and captured the native capital, Camulodūnum, now Colchester. From the base of London and Colchester three corps continued the conquest. The left wing, the Second Legion (under Vespasian, afterwards emperor), subdued the south; the centre, the Fourteenth and Twentieth Legions, subdued the midlands, while the right wing, the Ninth Legion, advanced through the eastern part

of the island. This strategy was at first triumphant. The lowlands of Britain, with their partly Romanized and partly scanty population and their easy physical features, presented no obstacle. Within three or four years everything south of the Humber and east of the Severn had been either directly annexed or entrusted, as protectorates, to native client-princes.

A more difficult task remained. The wild hills and wilder tribes of Wales and Yorkshire offered far fiercer resistance. There followed 30 years of intermittent hill fighting (A.D. 47-79). The precise details of the struggle are not known. Legionary fortresses were established at Wroxeter (for a time only), Caerleon (perhaps not till near the close of the period) and Chester, facing the Welsh hills, and at Lincoln in the north-east. The method of conquest was the erection and maintenance of small detached forts in strategic positions, each garrisoned by 500 or 1,000 men, and it was accompanied by a full share of those disasters which vigorous barbarians always inflict on civilized invaders. Progress was delayed too by the great revolt of Boadicea (*q.v.*) and a large part of the nominally conquered lowlands. Her rising was soon crushed, but the government was obviously afraid for a while to move its garrisons forward. Indeed, other needs of the empire caused the withdrawal of the Fourteenth Legion about 67. But the decade A.D. 70-80 was decisive. A series of three able generals commanded an army restored to its proper strength by the addition of Legio II. Adiutrix, and achieved the final subjugation of Wales and the first conquest of Yorkshire, where a legionary fortress at York was substituted for that at Lincoln.

The third and best-known, if not the ablest, of these generals, Iulius Agricola, moved on in A.D. 79 or 80 to the conquest of the farther north. He built forts in Cumberland, constructed a road (the Stanegate) from Carlisle to Corbridge, and pushed on across Cheviot into Scotland, where he established between the Clyde and Forth a temporary frontier, guarded by a line of posts, the most certainly identifiable of which is that at Bar hill. Presently he advanced into Caledonia and won a "famous victory" at Mons Graupius (sometimes, but incorrectly, spelt Grammpius), the site of which is doubtful, though it has given to the world the modern name of the Grampian hills. He dreamt even of invading Ireland, and thought it an easy task. The home government judged otherwise. Jealous possibly of a too brilliant general, certainly averse from costly and fruitless campaigns and needing the Legio II. Adiutrix for work elsewhere, it recalled both governor and legion, while it still endeavoured to cling to the ground that had been won (*see CALEDONIA*).

Precisely what happened after Agricola's departure, no one can tell. For 30 years (A.D. 85-115) the military history of Britain is little better than a blank; though we know that it was troubled. When the mists clear, we are in an altered world. About 115 or 120 the northern Britons rose in revolt and destroyed the Ninth Legion, posted at York, which would bear the brunt of any northern rebellions. The land beyond Cheviot was lost. In 122 the second reigning emperor who crossed the ocean, Hadrian, came himself to Britain, brought the Sixth Legion to replace the Ninth, and introduced the frontier policy of his age. For over 70m. from Tyne to Solway, more exactly from Wallsend to Bowness, he built a continuous rampart, with a ditch in front of it, a number of small forts along it, one or two outposts a few miles to the north of it, and some detached forts (the best-known is on the hill above Maryport) guarding the Cumberland coast beyond its western end; to move all these it must have been necessary to reduce the garrisons further south. The details of Hadrian's work are imperfectly known, for though many remains survive, it is hard to disentangle them. But that he has the best title to be regarded as the builder of the wall is proved alike by literature and by inscriptions. The meaning of the scheme is equally certain. It was to be, as it were, a Chinese wall, marking the definite limit of the Roman world. It was now declared, not by the secret resolutions of cabinets, but by the work of the spade marking the solid earth for ever, that the era of conquest was ended.

But empires move, though rulers bid them stand still. Whether the land beyond Hadrian's wall became temptingly peaceful or

remained in vexing disorder, our authorities do not say. We know only that about 142 Hadrian's successor, Antoninus Pius, acting through his general Lollius Urbicus, advanced from the Tyne and Solway frontier to the narrower isthmus between Forth and Clyde, 36m. across, which Agricola had fortified before him. Here he reared a continuous rampart with a ditch in front—fair-sized forts, probably 19 in number, built, as a rule, so

FROM "SOCIAL ENGLAND" (CASSELL & CO.)

FIG. 1.—HADRIAN'S WALL, THE NORTHERN BOUNDARY OF ROMAN BRITAIN, BUILT BY THE EMPEROR HADRIAN, C. A.D. 122. IT WAS 70M. IN LENGTH, EXTENDING FROM THE TYNE, ON THE NORTH SEA, TO SOLWAY FIRTH, ON THE IRISH SEA

as to abut directly upon it—and a connecting road running from end to end. An ancient writer states that the rampart was made of regularly laid sods. Excavation has proved that this is true so far as the greater part of it is concerned, but that for 10m. at the eastern end the body of the structure consisted largely of clay. The work still survives visibly, though in varying preservation, except in the agricultural districts near its two ends. Occasionally, as at Croyhill (near Kilsyth), at Seabegs wood, and in the covers of Bonny-side (3m. west of Falkirk), wall and ditch and even road can be distinctly traced, while the sites of many of the forts are plain to practised eyes. Six of these forts have been excavated. All show the ordinary features of Roman *castella*, though they differ more than one would expect in forts built at one time by one general. In every case the barrack-rooms were of wood, and the headquarters buildings, the storehouses and the baths of stone. In size the enclosures range from just over one acre to just under seven. Nor was the character of the defences uniform. Balmuildy and Castlecary were walled with stone, whereas the ramparts of old Kilpatrick, Bar hill, and Rough castle were of sods, those of Mumrills of clay. Rough castle is remarkable for the astonishing strength of its ramparts and ravelins, as well as for a series of defensive pits, reminiscent of Caesar's *lilia* at Alesia, but which may belong to an earlier Agricola fort. They were plainly intended to break an enemy's charge, and were either provided with stakes to impale the assailant or covered over with hurdles or the like to deceive him. Besides the 19 forts on the wall, one or two outposts seem to have been held at Ardoch and elsewhere along the natural route which runs by Stirling and Perth to the lowlands of the east coast.

The new frontier was reached from the south by two roads. One, known in mediaeval times as Dere street and misnamed Watling street by modern antiquaries, ran from Corbridge on the Tyne past Otterburn, crossed Cheviot near Makendon camps, and passed by an important fort at Newstead near Melrose, and others at Inveresk and Cramond (outside of Edinburgh), to the eastern end of the wall. The second starting from Carlisle, ran to Birrens, a Roman fort near Ecclefechan, and thence, by a line not yet explored and indeed not at all certain, to Carstairs and the west end of the wall. A fort at Lyne near Peebles suggests the existence of an intermediate link between them. There is nothing to indicate that the erection of the wall of Pius meant

the abandonment of the wall of Hadrian. Rather, both barriers were held together, and the district between them was regarded as a military area, outside the range of civilization. The advance, however, entailed a heavy demand on the man-power available, and it is not surprising to find that just at this time many of the forts in Wales were dismantled, that part of the island being now completely subdued.

The work of Pius brought no long peace. Sixteen years later disorder broke out in north Britain, apparently in the district between the Cheviots and the Derbyshire hills, and was repressed with difficulty after four or five years' fighting. Eighteen or 20 years later still (180–185) another war broke out with a different issue. The Romans were driven south of Cheviot, and perhaps even farther. The government of Commodus, feeble in itself and vexed by many troubles, could not repair the loss, and the civil wars which soon raged in Europe (193–197) gave the Caledonians further chance. It was not till 208 that Septimius Severus could turn his attention to the island. He came thither in person, conducted a punitive expedition into Caledonia, set himself to consolidate the position once more, and then, in the fourth year of his operations, died at York. Amid much that is uncertain and even legendary about his work in Britain, this is plain, that he fixed on the line of Hadrian's wall as his substantive frontier. His successors, Caracalla and Severus Alexander (211–235), accepted the position, and many inscriptions refer to building or rebuilding executed by them for the greater efficiency of the frontier defences. The conquest of Britain was at last over. The wall of Hadrian remained for nearly 200 years more the northern limit of Roman power in the extreme west.

## II. The Province of Britain and its Military System.—

Geographically, Britain consists of two parts: (1) the comparatively flat lowlands of the south, east and midlands, suitable for agriculture and open to easy intercourse with the continent, *i.e.*, with the rest of the Roman empire; (2) the district consisting of the hills of Devon and Cornwall, of Wales and of northern England, regions lying more, and often very much more, than 600ft. above the sea, scarred with gorges and deep valleys, mountainous in character, difficult for armies to traverse, ill fitted for peaceful pursuits. These two parts of the province differ also in their history. The lowlands, as we have seen, were conquered easily and quickly. The uplands were hardly subdued completely till the end of the 2nd century. They differ, thirdly, in the character of their Roman occupation. The lowlands were the scene of civil life. Towns, villages and country houses were their prominent features; troops were hardly seen in them save in some fortresses on the edge of the hills and in a chain of forts built in the 4th century to defend the south and south-east coast, the so-called Saxon shore. The uplands of Wales and the north presented another spectacle. Here civil life was almost

FIG. 2.—DIAGRAM SHOWING A SECTION THROUGH HADRIAN'S WALL

wholly absent. No country town or country house has been found more than 20m. north of York or west of Monmouthshire. The hills were one extensive military frontier, covered with forts and strategic roads connecting them, and devoid of town life, country houses, farms or peaceful civilized industry. This geographical division was not reproduced by Rome in any administrative partition of the province. At first the whole was governed by one *legatus Augusti* of consular standing. Septimius Severus made it two provinces, superior and inferior, the former of which included Caerleon and Chester, the latter Lincoln, York,

and apparently Hadrian's wall, but we do not know how long this arrangement lasted. In the 4th century there were five provinces, Britannia Prima and Secunda, Flavia and Maxima Caesariensis and (for a while) Valentia, ruled by *praesides* and *consulares* under a *vicarius*, but the only thing known of them is that Britannia Prima included Cirencester.

The army which guarded or coerced the province consisted, from the time of Hadrian onwards, of (1) three legions, the Second at Isca Silurum (Caerleon-on-Usk, *q.v.*), the Sixth at Eburacum (*q.v.*; now York), the Twentieth at Deva (*q.v.*; now Chester), a total of some 15,000 heavy infantry; and (2) a large but uncertain number of auxiliaries, troops of the second grade, organized in infantry cohorts or cavalry *alae*, each 500 or 1,000 strong, and posted in *castella* nearer the frontiers than the legions. The legionary fortresses were large rectangular enclosures of 50 or 60 acres, surrounded by strong walls of which traces can still be seen in the lower courses of the north and east town-walls of Chester, in the abbey gardens and elsewhere at York, and on the south side of Caerleon. The auxiliary *castella* were likewise square or oblong in shape but were hardly a tenth of the size, varying generally from three to six acres according to the size of the regiment and the need for stabling. Of these about 100 are known. The internal arrangements follow one general plan, but in some cases the buildings within the walls are all of stone, while in others, principally (it seems) forts built before 150, wood is used freely and only the few principal buildings seem to have been constructed throughout of stone. Chief among these latter, and in the centre of the whole fort, was the headquarters, in Lat. *Principia* or *Praetorium*. This was a rectangular structure with only one entrance which gave access, first, to a small cloistered court, then to a second open court, and finally to a row of three, five, or even seven rooms containing the shrine for official worship, the treasury and other offices. Close by were officers' quarters, generally built round a tiny cloistered court, and substantially constructed storehouses with buttresses and dry basements. These filled the middle third of the fort. At the two ends were barracks for the soldiers. No space was allotted to private religion or domestic life. The shrines which voluntary worshippers might visit, the public bath-house (as a rule), and the cottages of the soldiers' wives, camp followers, etc., lay outside the walls. Such were nearly all the Roman forts in Britain. They differ somewhat from Roman forts in Germany or other provinces, though most of the differences arise from the different usage of wood and of stone in various places.

Forts of this kind were dotted all along the military roads of the Welsh and northern hill-districts. In Wales a road ran from Chester past a fort at Caer-hun (near Conway) to a fort at Carnarvon (Segontium). A similar road ran along the south coast from Caerleon-on-Usk past a fort at Cardiff and perhaps others to Carmarthen and beyond. A third, roughly parallel to the shore of Cardigan bay, with forts at Llanio, Pennal, Tomen-y-mur (near Festiniog), and Caer Llugwy, connected the northern and southern roads, while the interior was held by a system of roads and forts not yet fully understood but discernible at such points as Caer-gai on Bala lake, Caersws, Castell Collen near Llandrindod Wells, the Gaer near Brecon, Merthyr and Gellygaer. In the north of Britain we find three principal roads. One led due north from York past forts at Catterick bridge, Pierce-bridge, Binchester, Lanchester, Ebchester to the wall and to Scotland, while branches through Chester-le-Street reached the Tyne bridge (Pons Aelius) at Newcastle and the Tyne mouth at South Shields. A second road, turning north-west from Catterick bridge, mounted the Pennine chain by way of forts at Rokeby, Bowes and Brough-under-Stainmoor, descended into the Eden valley, where it joined the third route, reaching Hadrian's wall near Carlisle (Luguvallium) by way of Old Penrith (Voreda), and running on to Birrens. The third route, starting from Chester and passing up the western coast, is more complex, and exists in duplicate, the result perhaps of two different schemes of road-making. Forts in plenty can be detected along it, notably Manchester (Mancunium or Mamucium), Ribchester (Bremeten-

Watercrook near Kendal, Waterhead near the hotel of that name on Ambleside, Hardknott above Eskdale, Ravenglass (probably Clanoventa), Maryport (Uxellodūnum), and Old Carlisle (possibly Petrianae). In addition, two or three cross roads, not yet sufficiently explored, maintained communication between the troops in Yorkshire and those in Cheshire and Lancashire. This road system bears plain marks of having been made at different times, and with different objectives, but we have no evidence that any one part was abandoned when any other was built. In general, however, it is clear that at no period were all the Roman forts in Britain simultaneously occupied. Garrisons were moved elsewhere as the country round them grew quieter. Thus, Gellygaer in South Wales and Hardknott in Cumberland have yielded nothing later than the opening of the 2nd century. On the other hand, forts which had been abandoned might be restored if circumstances changed. Thus, in Wales some of those which had been dismantled under Pius, were rebuilt by Severus, notably Segontium.

Besides these detached forts and their connecting roads, the north of Britain was defended by Hadrian's wall (figs. 1 and 2). The history of this wall has been given above. The actual works are threefold. First, there is that which to-day forms the most striking feature of the whole, the wall of stone 6-8 ft. thick, and originally perhaps 14 ft. high or a little higher, with a deep ditch in front, and forts (17 at very irregular intervals) and "mile castles" and turrets (both much more regularly spaced) and a connecting road behind it. On the high moors between Chollerford and Gilsland its traces are still plain, as it climbs from hill to hill and winds along perilous precipices. Secondly, there is, to the south of the wall, the so-called "Vallum," in reality no *vallum* at all, but a broad flat-bottomed ditch out of which the earth has been cast up on either side into regular and continuous mounds that resemble ramparts. Thirdly, to the west of Birdoswald fort there were discovered in 1895 the remains of a previously unknown wall, constructed of sods laid in regular courses, with a ditch in front. This turf wall can be traced for 1½ m., running roughly parallel to the stone wall, with the line of which its ends ultimately coincide. It is certainly older than the other and, as our ancient writers mention two wall-builders, Hadrian and Septimius Severus, it was at first inferred that Hadrian built his wall of turf and Severus reconstructed it in stone. Recent excavation has shown this attractive theory to be untenable by proving, first, that even in the section where both walls appear, the mile castles and turrets on the stone wall are of Hadrianic date and, second, that the ditch of the turf wall was deliberately filled up after it had been open for only a brief period.

The meaning of the *vallum* has been much discussed. John Hodgson and Bruce, the local authorities of the 19th century supposed that it was erected to defend the wall from southerly insurgents. Others have ascribed it to Agricola, or have thought it to be the wall of Hadrian, or even assigned it to pre-Roman natives. It is now clear that it is a Roman work, no older than Hadrian, and that it was not intended, like the wall, for military defence, but merely as a line of civil or legal delimitation. It is undoubtedly not earlier than certain of the forts, since it swings to the south to avoid them, and at some time in its history was branched by having a series of causeways laid across it, at intervals which seldom exceed 40 or 50 yards. Certain of the forts, on the other hand, are undoubtedly earlier than the stone wall, since this is built either wholly or partially over the north ends of their east and west ditches. Further, in at least two instances (Birdoswald and Chesters) the fort was practically doubled in size before the stone wall was erected. These data have suggested to the excavators the following provisional hypothesis as to the sequence of events, all of them compressing into a space of about seven years—(a) establishment of a line of small forts, with or without the *vallum*; (b) enlargement of some of the forts, and construction of the *vallum*, if not already in existence; (c) breaching of the *vallum*, and building of a stone wall as a link between the forts. The hypothesis accounts

notably (1) the turf wall and (2) a stone foundation 11 ft. wide discovered in 1925, running for a mile west of the fort of Aesica (Great Chesters) immediately in front of the stone wall, beneath which it finally disappears. Much spade-work remains to be done before a completely satisfactory solution is in sight.

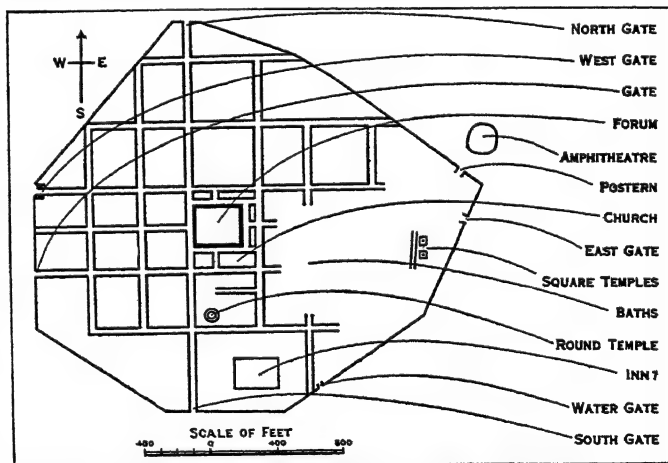

**III. The Civilization of Roman Britain.**—Behind these formidable garrisons, sheltered from barbarians and in easy contact with the Roman empire, stretched the lowlands of southern and eastern Britain. Here a civilized life grew up, and Roman culture spread. This part of Britain became Romanized. In the lands looking on to the Thames estuary (Kent, Essex, Middlesex) the process had perhaps begun before the Roman conquest. It was continued after that event, and in two ways. To some extent it was definitely encouraged by the Roman government, which here, as elsewhere, founded towns peopled with Roman citizens—generally discharged legionaries—and endowed them with franchise and constitution like those of the Italian municipalities. It developed still more by its own automatic growth. The coherent civilization of the Romans was accepted by the Britons, as it was by the Gauls, with something like enthusiasm. Encouraged perhaps by sympathetic Romans, spurred on still more by their own instincts, and led no doubt by their nobles, they began to speak Latin, to use the material resources of Roman civilized life, and in time to consider themselves not the unwilling subjects of a foreign empire, but the British members of the Roman state. The steps by which these results were reached can to some extent be dated. Within a few years of the Claudian invasion a *colonia*, or municipality of time-expired soldiers, had been planted in the old native capital of Colchester (Camulodūnum), and, though it served at first mainly as a fortress and thus provoked British hatred, it soon came to exercise a civilizing influence. At the same time the British town of Verulamium (St. Albans) was thought sufficiently Romanized to deserve the municipal status of a *municipium*, which at this period differed little from that of a *colonia*. London became important. Romanized Britons must now have begun to be numerous. In the great revolt of Boadicea (61) the nationalist party seem to have massacred many thousands of them along with actual Romans. Fifteen or 20 years later, the movement increases. Towns spring up, such as Silchester, laid out in Roman fashion, furnished with public buildings of Roman type, and filled with houses which are Roman in fittings if not in plan. The baths of Bath (Aquæ Sulis) are exploited. Another *colonia* is planted at Lincoln (Lindum), and a third at Gloucester (Glevum) in 96. A new "chief judge" is appointed for increasing civil business. The tax-gatherer and recruiting officer begin to make their way into the hills. During the 2nd century progress was perhaps slower, hindered doubtless by the repeated risings in the north. It was not till the 3rd century that country houses and farms became common in most parts of the civilized area. In the beginning of the 4th century the skilled artisans and builders, and the cloth and corn of Britain were equally famous on the continent. This probably was the age when the prosperity and Romanization of the province reached its height. By this time the town populations and the educated among the country-folk spoke Latin, and Britain regarded itself as a Roman land, inhabited by Romans and distinct from outer barbarism.

The civilization which had thus spread over half the island was genuinely Roman, identical in kind with that of the other western provinces of the empire, and in particular with that of northern Gaul. But it was defective in quantity. The elements which compose it are marked by smaller size, less wealth and less splendour than the same elements elsewhere. It was also uneven in its distribution. Large tracts, in particular Warwickshire and the adjoining midlands, were very thinly inhabited. Even densely peopled areas like north Kent, the Sussex coast, west Gloucestershire and east Somerset, immediately adjoin areas like the Weald of Kent and Sussex where Romano-British remains hardly occur.

The administration of the civilized part of the province, while subject to the governor of all Britain, was practically entrusted to local authorities. Each Roman municipality ruled itself and a territory, perhaps as large as a small county, which belonged to it. Some districts formed part of the Imperial domains, and were

administered by agents of the emperor. The rest, by far the larger portion of the country, was divided up among the old native tribes or cantons, some ten or 12 in number, each grouped round some country town where its council (*ordo*) met for cantonal business. This cantonal system closely resembles that which we find in Gaul. It is an old native element recast in Roman form, and well illustrates the Roman principle of local government by devolution.

In the general framework of Romano-British life the two chief features were the town, and the *villa*. Apart from Luguvalium (Carlisle) and Corstopitum (Corbridge upon Tyne), which lay within the military area and were really of the nature of "bazaars" (as it were) for the soldiers of the frontier garrison, the towns of the province, as we have already implied, fall into two classes. Five modern cities, Colchester, Lincoln, York, Gloucester and St. Albans, stand on the sites, and in some fragmentary fashion bear the names of five Roman municipalities founded by the Roman government with special charters and constitutions. All of these reached a considerable measure of prosperity. None of them rivals the greater municipalities of other provinces. Besides them we trace a larger number of country towns, varying much in size, but all possessing in some degree the characteristics of a town. The chief of these seem to be cantonal capitals, probably developed out of the market centres or capitals of the Celtic tribes before the Roman conquest. Such are Isurium Brigantum (Aldborough), capital of the Brigantes, 12m. north-west of York and the most northerly Romano-British town; Ratae, now Leicester, capital of the Coritani; Viroconium, now Wroxeter, near Shrewsbury, capital of the Cornovii; Venta Silurum, now Caerwent, near Chepstow; Corinium, now Cirencester, capital of the Dobuni; Isca Dumnoniorum, now Exeter, the most westerly of these towns; Durnovaria, now Dorchester, in Dorset, capital of the Durotriges; Venta Belgarum, now Winchester; Calleva Atrebatum, now Silchester, rom. south of Reading; Durovernum Cantiacorum, now Canterbury; and Venta Icenorum, now Caister-by-Norwich. Besides these country towns, Londinium (London) was a rich and important trading town, as the remarkable objects discovered in it abundantly prove, centre of the road system, and the seat of the finance officials of the province, while Aquæ Sulis (Bath) was a spa provided with splendid

GENERAL PLAN OF SILCHESTER (CALLEVA ATREBATUM)

Despite its irregular outline, Silchester furnishes a good example of the chess-board system of planning introduced into the West by the Romans who had received it from the East, through the expedition of Alexander the Great

baths, and a richly adorned temple of the native patron deity, Sul or Sulis, whom the Romans called Minerva. Many smaller places, too, for example, Magnæ or Kenchester near Hereford, Durobrivæ or Rochester in Kent, another Durobrivæ near Peterborough, a site of uncertain name near Cambridge, another of uncertain name near Chesterford, exhibited some measure of town life. London, one of the larger cities of the western empire, may well have had a character of its own, but direct evidence as to this is unfortunately lacking. Of the other towns we can form a good general idea through the excavations that have been carried out

at Silchester, Caerwent and Wroxeter. Public life centred round the forum and the adjoining basilica. Here the local authorities had their offices, justice was administered, traders trafficked, citizens and idlers gathered. In fig. 3, though we cannot apportion the rooms to their precise uses, the great hall was plainly the basilica, for meetings and business; the rooms behind it were perhaps law courts, and some of the rooms on the other three sides of the quadrangle may have been shops. The temples might be either square or round, and at Silchester there was a small Christian church of the so-called "basilican" type, of which many examples have been found in other countries, especially in Roman Africa. A suite of public baths was always a prominent feature, and outside the walls there was usually an amphitheatre. The private houses were of two types. They consisted either of a row of rooms, with a corridor along them, and perhaps one or two additional rooms at one or both ends, or of three such corridors and rows of rooms, forming three sides of a large square open yard. They were detached houses, standing each in its own garden, and not forming terraces or rows. They differ widely from the town houses of Rome and Pompeii; they are less unlike some of the country houses of Italy and Roman Africa, but their real parallels occur in Gaul, and they may be Celtic types modified to Roman use—like Indian bungalows. Their internal fittings—hypocausts, frescoes, mosaics—are everywhere Roman. The largest Silchester house, with a special annex for baths, is usually taken to be a guest-house or inn for travellers between London and the west.

The streets vary in width. The intersect regularly at right angles, dividing the town into square blocks, like modern Mannheim or Turin, according to a Roman system usual in both Italy and the provinces, and derived ultimately from Babylon and the East through Alexander the Great and his successors. The walls are often later than the streets, having been erected when the peace of the province began to be seriously threatened by barbarian inroads. The inference suggested by the appearance of the chess-board system of town-planning is confirmed by the testimony of the numberless small objects recovered in the course of the excavations—coins, pottery, window and bottle and cup glass, bronze ornaments, iron tools, etc. Few of these are individually notable. Traces of late Celtic art are singularly absent; Roman fashions rule supreme, and inscriptions show that even the lower classes here spoke and wrote Latin. Outside the walls there are but slight traces of inhabitation, a fact which is significant of the economic position of the towns of Roman Britain. We may conclude that these towns were thoroughly Romanized, peopled with Roman-speaking citizens, furnished with Roman appurtenances, living in Roman ways, but not very large, not very rich, a humble witness to the assimilating power of the Roman civilization.

The country, as opposed to the towns, of Roman Britain seems to have been divided into estates, commonly (though perhaps incorrectly) known as "villas." Many examples survive, some of them large and luxurious country-houses, some mere farms, constructed usually on one of the two patterns described in the account of the towns above. The inhabitants were plainly as various—a few of them great nobles and wealthy landowners, others small farmers or possibly bailiffs. Some of these estates were worked on the true "villa" system, by which the lord occupied the "great house," and cultivated the land close round it by slaves, while he let the rest to half-free *coloni*. But other systems may have prevailed as well. Among the most important country-houses are those of Bignor in west Sussex, and Woodchester and Chedworth in Gloucestershire. At the other extreme were the villages, whose remains can be detected in the Thames valley and elsewhere, and which housed the humbler members of the population.

The wealth of the country was principally agrarian, and the needs of the army of occupation must have helped to stimulate production. Wheat and wool were exported in the 4th century, when, as we have said, Britain was especially prosperous. But the details of the trade are unrecorded. More is known of the lead and iron mines which, at least in the first two centuries,

were worked in many districts—lead (from which silver was extracted) in Somerset, Shropshire, Flintshire and Derbyshire; iron in the west Sussex Weald, the Forest of Dean, and (to a slight extent) elsewhere. Other minerals were less notable. The gold mentioned by Tacitus proved scanty, although there seem to be clear indications of Roman gold-mining in Wales. The Cornish tin, according to present evidence, was worked comparatively little, and perhaps most in the later Empire.

Lastly, the roads. Here we must put aside all idea of "four great roads." That category is probably the invention of antiquaries, and certainly unconnected with Roman Britain (see *ERMINE STREET*). Instead, we may distinguish four main groups of roads radiating from London, and a fifth which runs obliquely. One road ran south-east to Canterbury and the Kentish ports, of which Richborough (Rutupiae) was the most frequented. A second ran west to Silchester, and thence by various branches to Winchester, Exeter, Bath, Gloucester and South Wales. A third, known afterwards to the English as Watling street, ran by St. Albans wall and near Lichfield (Lectocetum) to Wroxeter and Chester. It also gave access by a branch to Leicester and Lincoln. A fourth served Colchester, the eastern counties, Lincoln and York. The fifth is that known to the English as the Fosse, which joins Lincoln and Leicester with Cirencester, Bath and Exeter. Besides these five groups, an obscure road, called by the Saxons Akeman Street, gave alternative access from London through Alchester (outside of Bicester) to Bath, while another obscure road winds south from near Sheffield, past Derby and Birmingham, and connects the lower Severn with the Humber. By these roads and their various branches the Romans provided adequate communications throughout the lowlands of Britain.

**IV. The End of Roman Britain.**—About 286 Carausius, admiral of the "Classis Britannica," quarrelled with the central government and proclaimed himself emperor. He remained in control of the island until 293, when he was murdered by one of his own officers, Allectus, who essayed to succeed him. By this time, however, the authorities at Rome had resolved on reconquest. An expedition under the personal command of the future emperor, Constantius Chlorus, successfully evaded the waiting ships of Allectus, and the usurper was slain in a land-battle. Extensive changes in the distribution of the garrison seem to have followed. Danger threatened, not only from the Picts beyond Hadrian's wall, but also from the sea. It may have been now that Caerleon was evacuated and the Second Legion sent elsewhere. At all events a special coast defence, reaching from the Wash to Spithead, was established against Saxon pirates: there were forts at Brancaster, Burgh Castle (near Yarmouth), Walton (near Felixstowe), Bradwell (at the mouth of the Colne and Blackwater), Reculver, Richborough, Dover and Lympne (all in Kent), Pevensey in Sussex, and Porchester near Portsmouth. The Irish (Scoti), too, were becoming increasingly aggressive. It is, therefore, not surprising that a new fort should have been erected at Cardiff and perhaps one on the Isle of Wight. For a time these measures were effective and the province prospered. But after about 350 the barbarian assaults became more frequent and more terrible. The building of a series of stone watch-towers along the Yorkshire coast, from the Tees to Flamborough head, is very significant.

At the end of the century Magnus Maximus, claiming to be emperor, withdrew many troops from Britain and a later pretender did the same. Early in the 5th century the Teutonic conquest of Gaul cut the island off from Rome. This does not mean that there was any great "departure of the Romans." The central government simply ceased to send the usual governors and high officers. The Romano-British were left to themselves. Their position was weak. Their fortresses lay in the north and west, while the Saxons attacked the east and south. Their trained troops, and even their own numbers, must have been few. It is intelligible that they followed a precedent set by Rome in that age, and hired Saxons to repel Saxons. But they could not command the fidelity of their mercenaries, and the Saxon peril only grew greater. It would seem as if the Romano-Britons were speedily driven from the east of the island, and as if the Saxons,

though apparently unable to gain a hold on the western uplands, were able to prevent the natives from recovering the lowlands. Thus driven from the centres of Romanized life, from the region of walled cities and civilized houses, into the hills of Wales and the north-west, the provincials underwent an intelligible change. The Celtic element, never quite extinct in those hills and, like most forms of barbarism, reasserting itself in this wild age—not without reinforcement from Ireland—challenged the remnants of Roman civilization and in the end absorbed them. The Celtic language reappeared; the Celtic art emerged from its shelters in the west to develop in new and mediaeval fashions.

**ANCIENT AUTHORITIES.**—The principal references to early Britain in classical writers occur in Strabo, Diodorus, Julius Caesar, the elder Pliny, Tacitus, Ptolemy, Cassius Dio and Ammianus Marcellinus, and in the lists of the Antonine Itinerary (probably about A.D. 210–230; ed. Parthey, 1848), the *Notitia Dignitatum* (about A.D. 400; ed. Seeck, 1876), and the Ravennas (7th century *réchauffé*; ed. Parthey 1860). The chief passages are printed in Petrie's *Monumenta Hist. Britann.* (1848), and (alphabetically) in Holder's *Aliceltischer Sprachschatz* (1896–1908). The Roman inscriptions have been collected in *Corpus Inscriptionum Latin.* vii. (1873), and in the periodical *Ephemeris epigraphica* (iii., iv., vii. and particularly ix.).

**BIBLIOGRAPHY.**—(a) For Pre-Roman Britain: T. R. Holmes, *Ancient Britain* (1907), who cites numerous authorities; R. E. M. Wheeler, *Prehistoric and Roman Wales* (1925); Sir Arthur Keith, *The Antiquity of Man* (1925); D. A. E. Garrod, *The Upper Palaeolithic Age in Britain* (1926).

### ANGLO-SAXON BRITAIN

**History.**—The history of Britain after the withdrawal of the Roman troops is extremely obscure, but there can be little doubt that for many years the inhabitants were exposed to devastating raids by the Picts and Scots. According to Gildas it was for protection against these incursions that the Britons decided to call in the Saxons. Their allies soon obtained a decisive victory, but subsequently turned their arms against the Britons themselves, alleging that they had not received sufficient payment for their services. A different account, probably of English origin, may be traced in the *Historia Brittonum*, according to which the first leaders of the Saxons, Hengest and Horsa, came as exiles, seeking the protection of the British king, Vortigern. Having embraced his service they quickly expelled the northern invaders. Eventually, however, they overcame the Britons through treachery, by inducing the king to allow them to send for large bodies of their own countrymen. It was to these adventurers, according to tradition, that the kingdom of Kent owed its origin. The story is in itself by no means improbable, while the dates assigned to the first invasion by various Welsh, Gaulish, and English authorities, with one exception, all fall within about a quarter of a century, viz., between the year 428 and the joint reign of Martian and Valentinian III. (450–455).

For the subsequent course of the invasion the information is most meagre and unsatisfactory. According to the Anglo-Saxon Chronicle the kingdom of Sussex was founded by a certain Ella or Aelle, who landed in 477, while Wessex owed its origin to Cerdic, who arrived some 18 years later. No value, however, can be attached to these dates; indeed, in the latter case the story itself is open to suspicion (see *WESSEX*). For the movements which led to the foundation of the more northern kingdoms we have no evidence worth consideration, nor do we know even approximately when they took place. But the view that the invasion was effected throughout by small bodies of adventurers acting independently of one another, and that each of

the various kingdoms owes its origin to a separate enterprise, has little probability. Bede states that the invaders belonged to three different nations, Kent and southern Hampshire being occupied by Jutes (*q.v.*), while Essex, Sussex, and Wessex were founded by the Saxons, and the remaining kingdoms by the Angli (*q.v.*). The peculiarities of social organization in Kent certainly tend to show that this kingdom had a different origin from the rest; but the evidence for the distinction between the Saxons and the Angli is much less satisfactory (see *ANGLO-SAXONS*). The royal family of Essex may have been of Saxon origin (see *ESSEX*), but on the other hand the West Saxon royal family claimed to be of the same stock as that of Bernicia, and their connections in the past seem to have lain with the Angli.

There is no doubt that the first invasion was followed by a long period of warfare between the natives and the invaders, in which the latter gradually strengthened their hold on the conquered territories. It is probable that by the end of the 5th century all the eastern part of Britain, at least as far as the Humber, was in their hands. The first important check was received at the siege of "Mons Badonicus" in the year 517 (*Ann. Cambr.*), or perhaps rather some 15 or 20 years earlier. According to Gildas this event was followed by a period of peace for at least 44 years. In the latter part of the 6th century, however, the territories occupied by the invaders seem to have been greatly extended. In the south the West Saxons are said to have conquered first Wiltshire and then all the upper part of the Thames valley, together with the country beyond as far as the Severn. The northern frontier also seems to have been pushed considerably farther forward, perhaps into what is now Scotland, and it is probable that the basin of the Trent, together with the central districts between the Trent and the Thames, was conquered about the same time, though of this there is no record. Again, the destruction of Chester about 615 was soon followed by the overthrow of the British kingdom of Elmet in south-west Yorkshire, and the occupation of Shropshire and the Lothians took place perhaps about the same period, that of Herefordshire probably somewhat later. In the south, Somerset is said to have been conquered by the West Saxons shortly after the middle of the 7th century. Dorset had probably been acquired by them before that time, while part of Devon seems to have come into their hands soon afterwards.

The area thus conquered was occupied by a number of separate kingdoms, each with a royal family of its own. The districts north of the Humber contained two kingdoms, Bernicia and Deira (*q.v.*), which were eventually united in Northumbria. South of the Humber, Lindsey seems to have had a dynasty of its own, though in historical times it was apparently always subject to the kings of Northumbria or Mercia. The upper basin of the Trent formed the nucleus of the kingdom of Mercia (*q.v.*), while farther down the east coast was the kingdom of East Anglia (*q.v.*). Between these two lay a territory called Middle Anglia, sometimes described as a kingdom, though whether it ever had a separate dynasty is not known. Essex, Kent, and Sussex (see articles on these kingdoms) preserve the names of ancient kingdoms, while the old diocese of Worcester grew out of the kingdom of the Hwicce (*q.v.*), with which it probably coincided in area. The south of England, between Sussex and "West Wales" (eventually reduced to Cornwall), was occupied by Wessex, which originally also possessed some territory to the north of the Thames. Lastly, even the Isle of Wight appears to have had a dynasty of its own. But these kingdoms were not always, or even normally, independent. When history begins, Aethelberht, king of Kent, was supreme over all the kings south of the Humber.

**Government.**—Internally the various states seem to have been organized on very similar lines. In every case we find kingly government from the time of the earliest records, and the institution certainly goes back to a date anterior to the invasion of Britain (see *OFFA*; *WERMUND*). The royal title, however, was frequently borne by more than one person. Sometimes we find one supreme king with a number of under-kings (*subreguli*); sometimes, especially in the smaller kingdoms, Essex, Sussex, and Hwicce, two or more kings, generally brothers, reign together

apparently on equal terms. For most of the 8th century Kent seems to have been divided into two kingdoms; but as a rule such divisions did not last beyond the lifetime of the kings who made the arrangement. The kings were, with very rare exceptions, chosen from one particular family in each state, the ancestry of which was traced back not only to the founder of the kingdom but, in a remoter degree, to a god. The members of such families were entitled to special wergilds, apparently six times as great as those of the higher class of nobles (*see below*).

The only other central authority in the state was the king's council or court (*theod, witan, concilium*). This body was made up partly of young warriors in constant attendance on the king, and partly of senior officials whom he called together from time to time. The terms used for the two classes by Bede are *milites* (*ministri*) and *comites*, for which the Anglo-Saxon version has *thegnas* and *gesithas* respectively. Both classes consisted in part of members of the royal family. But they were not confined to such persons or even to born subjects of the king. Indeed, we are told that popular kings like Oswine attracted young nobles to their service from all quarters. The functions of the council have been much discussed, and it has been claimed that they had the right of electing and deposing kings. This view, however, seems to postulate a greater feeling for constitutionalism than is warranted by the information at our disposal. The incidents which have been brought forward as evidence may with equal probability be interpreted as cases of profession or transference of personal allegiance. In other respects the functions of the council seem to have been deliberative. It was customary for the king to seek their advice and moral support on important questions, but there is nothing to show that he had to abide by the opinion of the majority.

For administrative purposes, each kingdom was divided into a number of districts under the charge of royal reeves (*cyninges gerefa, praefectus, praepositus*). These officials seem to have been located in royal villages (*cyninges tun, villa regalis*) or fortresses (*cyninges burg, urbs regis*), which served as centres and meeting-places (markets, etc.) for the inhabitants of the district, and to which their dues, both in payments and services, had to be rendered. The usual size of such districts in early times seems to have been 300, 600, or 1,200 hides. Much larger divisions containing 2,000, 3,000, 5,000, or 7,000 hides are also mentioned. To this category belong the shires of Wessex (Hampshire, Wiltshire, Berkshire, etc.), each of which had an earl (*aldormon, princeps, dux*) of its own, at all events from the 8th century onwards. Many, if not all, of these persons were members of the royal family, and it is not unlikely that they originally bore the kingly title. At all events they are sometimes described as *subreguli*.

**Social Organization.**—The officials mentioned above, whether of royal birth or not, were probably drawn from the king's personal retinue. In Anglo-Saxon society, as in that of all Teutonic nations in early times, the two most important principles were those of kinship and personal allegiance. If a man suffered injury it was to his relations and his lord, rather than to any public official, that he applied first for protection and redress. If he was slain, a fixed sum (*wergild*), varying according to his station, had to be paid to his relations, while a further but smaller sum (*manbot*) was due to his lord. These principles applied to all classes of society, and though strife within the family was by no means unknown, at all events in royal families, the actual slaying of a kinsman was regarded as the most heinous of all offences. Much the same feeling applied to the slaying of a lord—an offence for which no compensation could be rendered. How far the armed followers of a lord were entitled to compensation when the latter was slain is uncertain, but in the case of a king they received an amount equal to the wergild. Another important development of the principle of allegiance is to be found in the custom of heriots. In later times this custom amounted practically to a system of death-duties, payable in horses and arms or in money to the lord of the deceased. There can be little doubt, however, that originally it was a restoration to the lord of the military outfit with which he had presented his

man when he entered his service. The institution of thegnhood, *i.e.*, membership of the *comitatus* or retinue of a prince, offered the only opening by which public life could be entered. Hence it was probably adopted almost universally by young men of the highest classes. The thegn was expected to fight for his lord, and generally to place his services at his disposal in both war and peace. The lord, on the other hand, had to keep his thegns and reward them from time to time with arms and treasure.

The structure of society in England was of a somewhat peculiar type. In addition to slaves, who in early times seem to have been numerous, there were in Wessex and apparently also in Mercia three classes, described as *twelfhynde*, *sixhynde*, and *twi-hynde* from the amount of their wergilds, *viz.*, 1,200, 600, and 200 shillings respectively. It is probable that similar classes existed also in Northumbria, though not under the same names. Besides these terms there were others which were probably in use everywhere, *viz.*, *gesithcund* for the two higher classes and *ceorlisc* for the lowest. Indeed, these terms occur even in Kent, though the social system of that kingdom seems to have been essentially different. Here the wergild of the *ceorlisc* class amounted to 100 shillings, each containing 20 silver coins (*sceattas*), as against 200 shillings of four (in Wessex five) silver coins. Again, there was apparently but one *gesithcund* class in Kent, with a wergild of 300 shillings, while, on the other hand, below the *ceorlisc* class there were three classes of persons described as *laetas*, who probably corresponded to the *liti* or freedmen of the Continental laws, and possessed wergilds of 80, 60, and 40 shillings respectively. To these no analogy is found in the other kingdoms, though the poorer classes of Welsh freemen had wergilds varying from 120 to 60 shillings. This differential treatment of the various classes was not confined to the case of wergilds. It appears also in the compensations to which they were entitled for various injuries, in the fines to which they were liable, and in the value attached to their oaths. Generally, though not always, the proportions observed were the same as in the wergilds.

The nature of the distinction between the *gesithcund* and *ceorlisc* classes is nowhere clearly explained; but it was certainly hereditary and probably of considerable antiquity. We may perhaps define them as nobles and commons, though in view of the numbers of the higher classes it would probably be more correct to speak of gentry and peasants. The distinction between the *twelfhynde* and *sixhynde* classes was also in part at least hereditary, but there is good reason for believing that it arose out of the possession of land. The former consisted of persons who possessed, whether as individuals or families, at least five hides of land—which practically means a village—while the latter were landless, *i.e.*, probably without this amount of land. Within the *ceorlisc* class we find similar subdivisions, though they were not marked by a difference in wergild. The *gafolgelda* or *tributarius* (tribute-payer) seems to have been a ceorl who possessed at least a hide, while the *gebur* was without land of his own and received his outfit as a loan from his lord.

**Payments and Services.**—Reference has already been made to the dues rendered by different classes of the population, which the reeves in royal villages had to collect and superintend. The payments seem to have varied greatly according to the class from which they were due. Those rendered by landowners seem to have been known as *feorm* or *fostor*, and consisted of a fixed quantity of articles paid in kind. In Ine's Laws (cap. 70) there is a list of payments specified for a unit of ten hides, perhaps the normal holding of a *twelfhynde* man—though it may be nothing more than a mere fiscal unit in an aggregate of estates. The list consists of oxen, sheep, geese, hens, honey, ale, loaves, cheese, butter, fodder, salmon, and eels. Very similar specifications are found elsewhere. The payments rendered by the *gafolgelda* (*tributarius*) were known as *gafol* (*tributum*), as his name implies. Ine's Laws refer only to the *hwitel* or white cloak, which was to be of the value of sixpence per household (hide), and to barley, which was to be six pounds in weight for each worker. In later times many other payments occur both in money and in kind, some of which were doubtless in accordance with ancient custom. On the other hand the *gebur* seems not to have been liable to payments or

this kind, presumably because the land which he cultivated formed part of the *demesne* (*inland*) of his lord. The term *gafol*, however, may have been applied to the payments which he rendered to the latter.

The services required of landowners were very manifold in character. Probably the most important were military service (*fird*, *expeditio*) and the repairing of fortifications and bridges (*see* *TRINODA NECESSITAS*). In addition to these we find reference in charters of the 9th century to the keeping of the king's hunters, horses, dogs, and hawks, and the entertaining of messengers and other persons in the king's service. The duties of men of the *sixhynde* class, if they are to be identified with the *radcnihtas* (*radmanni*) of later times, probably consisted chiefly in riding on the king's (or their lord's) business. The services of the peasantry can only be conjectured from the custom of later times. Presumably their chief duty was to undertake a share in the cultivation of the *demesne* land. No doubt also the labour of repairing fortifications and bridges, though it was charged against the landowners, was in reality delegated by them to their dependents.

**Warfare.**—All classes are said to have been liable to the duty of military service. Hence, since the *ceorls* doubtless formed the bulk of the population, it has been thought that the Anglo-Saxon armies of early times were essentially peasant forces. The available evidence, however, gives little justification for such a view. The regulation that every five or six hides should supply a warrior was not a product of the Danish invasions, as is sometimes stated, but goes back at least to the beginning of the 9th century. Had the fighting material been drawn from the *ceorlisc* class a warrior would surely have been required from each hide, but for military service no such regulation is found. Again, the *fird* (*fyrð*) was composed of mounted warriors during the 9th century, though apparently they fought on foot, and there are indications that such was the case also in the 7th century. No doubt *ceorls* took part in military expeditions, but they may have gone as attendants and camp-followers rather than as warriors, their chief business being to make stockades and bridges, and especially to carry provisions. The serious fighting, however, was probably left to the *gesithcund* classes, who possessed horses and more or less effective weapons. Indeed, there is good reason for regarding these classes as essentially military.

The chief weapons were the sword and spear. The former were two-edged and on the average about 3ft. long. The hilts were often elaborately ornamented and sometimes these weapons were of considerable value. No definite line can be drawn between the spear proper and the javelin. The spear-heads which have been found in graves vary considerably in both form and size. Bows and arrows were certainly in use for sporting purposes, but there is no reason for believing that they were much used in warfare before the Danish invasions. They are very seldom met with in graves. The most common article of defensive armour was the shield, which was small and circular and apparently of quite thin lime-wood, the edge being formed probably by a thin band of iron. In the centre of the shield, in order to protect the hand which held it, was a strong iron boss, some 7in. in diameter and projecting about 3in. It is clear from literary evidence that the helmet (*helm*) and coat of chain mail (*byrne*) were also in common use. They are seldom found in graves, however, whether owing to the custom of heriots or to the fact that, on account of their relatively high value, they were frequently handed on from generation to generation as heirlooms. Greaves are not often mentioned. In later times the heriot of an "ordinary thegn" (*medema thegn*)—by which is meant apparently not a king's thegn but a man of the *twelfhynde* class—consisted of his horse with its saddle, etc., and his arms, or two pounds of silver as an equivalent of the whole. The arms required were probably a sword, helmet, coat of mail and one or two spears and shields. There are distinct indications that a similar outfit was fairly common in Ine's time, and that its value was much the same. One would scarcely be justified, however, in supposing that it was anything like universal; for the purchasing power of such a sum was at that time considerable,

representing as it did about 16–20 oxen or 100–120 sheep. It would hardly be safe to credit men of the *sixhynde* class in general with more than a horse, spear, and shield.

**Agriculture and Village Life.**—There is no doubt that a fairly advanced system of agriculture must have been known to the Anglo-Saxons before they settled in Britain. This is made clear above all by the representation of a plough drawn by two oxen in one of the very ancient rock-carvings at Tegneby in Bohuslän. In Domesday Book the heavy plough with eight oxen seems to be universal, and it can be traced back in Kent to the beginning of the 9th century. In this kingdom the system of agricultural terminology was based on it. The unit was the *sulung* (*aratrum*) or ploughland (from *sulh*, "plough"), the fourth part of which was the *geocled* or *geoc* (*jugum*), originally a yoke of oxen. An analogy is supplied by the *carucata* of the Danelagh, the eighth part of which was the *bouata* or "ox-land." In the 10th century the *sulung* seems to have been identified with the hide, but in earlier times it contained apparently two hides. The hide itself, which was the regular unit in the other kingdoms, usually contained 120ac. in later times and was divided into four *girda* (*virgatae*) or yardlands. But originally it seems to have meant simply the land pertaining to a household, and its area in early times is quite uncertain, though probably far less. For the acre also there was in later times a standard length and breadth, the former being called *furhlang* (furlong) and reckoned at one-eighth of a mile, while the *aecerbraedu* or "acre-breadth" (chain) was also a definite measure.

The husbandry was of a co-operative character. In the 11th century it was distinctly unusual for a peasant to possess a whole team of his own, and there is no reason for supposing the case to have been otherwise in early times; for though the peasant might then hold a hide, the hide itself was doubtless smaller and not commensurate with the ploughland. The holdings were probably not compact but consisted of scattered strips in common fields, changed perhaps from year to year, the choice being determined by lot or otherwise. For the method of cultivation there is little or no evidence. Both the "two-course system" and the "three-course system" may have been in use; but it is quite possible that in many cases the same ground was not sown more than once in three years. The prevalence of the co-operative principle was doubtless due in large measure to the fact that the greater part of England, especially towards the east, was settled not in scattered farms or hamlets but in compact villages with the cultivated lands lying around them.

The mill was another element which tended to promote the same principle. There can be little doubt that before the Anglo-Saxons came to Britain they possessed no instrument for grinding corn except the quern (*cweorn*), and in remote districts this continued in use until quite late times. The grinding seems to have been performed chiefly by female slaves, but occasionally we hear also of a donkey-mill (*esolcweorn*). The mill proper, however, which was derived from the Romans, as its name (*mylen*, from Lat. *molina*) indicates, must have come into use fairly early. In the 11th century every village of any size seems to have possessed one, while the earliest references go back to the 8th century. It is not unlikely that they were in use during the Roman occupation of Britain, and consequently that they became known to the invaders almost from the first. The mills were presumably driven for the most part by water, though there is a reference to a wind-mill as early as the year 833.

All the ordinary domestic animals were known. Cattle and sheep were pastured on the common lands appertaining to the village, while pigs, which (especially in Kent) seem to have been very numerous, were kept in the woods. Bee-keeping was also practised. In all these matters the invasion of Britain had brought about no change. The cultivation of fruit and vegetables on the other hand was probably almost entirely new. The names are almost all derived from Latin, though most of them seem to have been known soon after the invasion, at all events by the 7th century.

The question how far the villages were really new settlements is difficult to answer, for the terminations *-ham*, *-ton*, etc., cannot

be regarded as conclusive evidence. Thus, according to the Anglo-Saxon Chronicle (ann. 571), Bensington and Eynsham were formerly British villages. Even if the first part of Egonesham is English—which is by no means certain—it is hardly sufficient reason for discrediting this statement, for Canterbury (*Cantwara-burg*) and Rochester (*Hrofes ceaster*) were without doubt Roman places in spite of their English names. On the whole it seems likely that the cultivation of the land was not generally interrupted for more than a very few years; hence the convenience of utilizing existing sites of villages would be obvious, even if the buildings themselves had been burnt.

**Towns.**—Most of the cities of Roman Britain were situated within the territories eventually occupied by the invaders, and re-appear as towns in later times. Their history in the intervening period is wrapped in obscurity. Chester appears to have been deserted for three centuries after its destruction early in the 7th century, and in most of the other cases there are features observable in the situation and plan of the mediaeval town which suggest that its occupation had not been continuous. Yet London and Canterbury must have recovered a certain amount of importance quite early, at all events within two centuries after the invasion, and the same is probably true of York, Lincoln, and a few other places. The term applied to both the cities and the fortresses of the Romans was *ceaster* [Lat. *castra*], less frequently the English word *burg*. There is little or no evidence for the existence of towns other than Roman in early times, for the word *urbs* is merely a translation of *burg*, which was used for any fortified dwelling-place, and it is improbable that anything which could properly be called a town was known to the invaders before their arrival in Britain. The Danish settlements at the end of the 9th century and the defensive system initiated by King Alfred gave birth to a new series of fortified towns, from which the boroughs of the middle ages are mainly descended.

**Houses.**—Since houses were built entirely of perishable materials, wood and wattle, we are necessarily dependent almost wholly upon literary evidence for knowledge of this subject. Stone seems to have been used first for churches, but this was not before the 7th century, and we are told that at first masons were imported from Gaul. Indeed wood was used for many churches, as well as for most secular buildings, until a much later period. The walls were formed either of stout planks, laid together vertically or horizontally, or of posts at a short distance from one another, the interstices being filled up with wattlework daubed with clay. It is likely that the houses of wealthy persons were distinguished by ornamentation in carving and painting. The roof was high-pitched and covered with straw, hay, reeds, or tiles. The regular form of the buildings was rectangular, the gable sides probably being shorter than the others. There is little evidence of partitions inside, and in wealthy establishments the place of rooms seems to have been supplied by separate buildings within the same enclosure. The windows must have been mere openings in the walls or roof, for glass was not used for this purpose before the latter part of the 7th century. Stoves were known, but most commonly heat was obtained from an open fire in the centre of the building. Of the various buildings in a wealthy establishment the chief were the hall (*heall*), which was both a dining and reception room, and the "lady's bower" (*brydbur*), which served also as a bedroom for the master and mistress. To these must be added buildings for the attendants, kitchen, bakehouse, etc., and farm buildings. There is little or no evidence of the use of two-storeyed houses in early times, though in the 10th and 11th centuries they were common. The whole group of buildings stood in an enclosure (*tun*) surrounded by a stockade (*burg*), which perhaps rested on an earthwork, though this is disputed. Similarly the homestead of the peasant was surrounded by a fence (*edor*).

**Clothes.**—The chief material for clothing was at first no doubt wool, though linen must also have been used and later became fairly common. The chief garments were the coat (*roc*), the trousers (*brec*), and the cloak, for which there seem to have been a number of names (*hacele*, *sciccing*, *pad*, *hwitel*). To these we may add the hat (*haet*), belt (*gyrdel*), stockings (*hosa*), shoes

(*scoh*, *rifeling*), and gloves (*glof*). The *crusene* was a fur coat, while the *serc* or *smoc* seems to have been an undergarment, probably sleeveless. The whole attire was of national origin and had probably been in use long before the invasion of Britain. In the great bog-deposit at Thorsbjærg in Angel, which dates from about the 4th century, there were found a coat with long sleeves, a pair of long trousers with remains of socks attached, several shoes and portions of square cloaks, one of which had obviously been dyed green. The dress of the upper classes must have been somewhat gorgeous, especially when account is taken of the brooches and other ornaments which they wore. According to Jordanes the Swedes in the 6th century were splendidly dressed.

**Trade.**—The few notices of this subject which occur in the early laws seem to refer primarily to cattle-dealing. But there can be no doubt that a considerable import and export trade with the Continent had sprung up quite early. In Bede's time, if not before, London was resorted to by many merchants both by land and by sea. At first the chief export trade was probably in slaves. English slaves were to be obtained in Rome even before the end of the 6th century, as appears from the well-known story of Gregory the Great. Since the standard price of slaves on the Continent was in general three or four times as great as it was in England, the trade must have been very profitable. After the adoption of Christianity it was gradually prohibited by the laws. The nature of the imports during the heathen period may be learned chiefly from the graves, which contain many brooches and other ornaments of Continental origin, and also a certain number of silver, bronze and glass vessels. With the introduction of Christianity the ecclesiastical connection between England and the Continent brought about a large increase in the imports of secular as well as religious objects, and the frequency of pilgrimages by persons of high rank must have had the same effect. The use of silk (*seoluc*) and the adoption of the mancus (*see below*) point to communication, direct or indirect, with more distant countries. In the 8th century we hear frequently of tolls on merchant ships at various ports, especially London.

**Coinage.**—The earliest coins which can be identified with certainty are some silver pieces which bear in Runic letters the name of the Mercian king Aethelred (675–704). There are others, however, of the same type and standard (about 21 grains) which may be attributed with probability to his father Penda (d. 655). But it is clear from the laws of Aethelberht that a regular silver coinage was in use at least half a century earlier, and it is not unlikely that many unidentified coins may go back to the 6th century. These are fairly numerous and are either without inscriptions or, if they do bear letters at all, they seem to be mere corruptions of Roman legends. Their designs are derived from Roman or Frankish coins, especially the former, and their weight varies from about 10 to 21 grains, though the very light coins are rare. Anonymous gold coins, resembling Frankish trientes in type and standard (21 grains), are also fairly common, though they must have passed out of use very early, as the laws give no hint of their existence. Larger gold coins (*solidi*) are very rare. In the early laws the money actually in use appears to have been entirely silver. In Offa's time a new gold coin, the *mancus*, resembling in standard the Roman *solidus* (about 70 grains), was introduced from Mohammedan countries. The oldest extant specimen bears a faithfully copied Arabic inscription. In the same reign the silver coins underwent a considerable change in type, being made larger and thinner, while from this time onwards they always bore the name of the king (or queen or archbishop) for whom they were issued. The design and execution also became remarkably good. Their weight was at first unaffected, but probably towards the close of Offa's reign it was raised to about 23 grains, at which standard it seems to have remained, nominally at least, until the time of Alfred. It is to be observed that, with the exception of Burgred's coins and a few anonymous pieces, the silver was never adulterated. No bronze coins were current except in Northumbria, where they were extremely common in the 9th century.

Originally *scilling* ("shilling") and *sceatt* seem to have been the terms for gold and silver coins respectively. By the time of

BY COURTESY OF (1, 2, 3, 4, 6, 7, 8, 9, 11) THE TRUSTEES OF THE BRITISH MUSEUM. (5) THE DIRECTOR OF THE YORKSHIRE MUSEUM, YORK, (10) THE DIRECTOR OF THE NATIONAL MUSEUM OF ANTIQUITIES, EDINBURGH

#### JEWELLERY AND METAL CRAFTSMANSHIP OF EARLY BRITAIN

1. Glass drinking horn found at Kempston, Bedfordshire. 2. The Franks casket of whale's bone, about 8th century. 3. Silver penannular brooch, about 10th century, found in Cumberland. 4. Gold neck-chain, probably 2nd century, found near Backworth, Northumberland. 5. Embossed Anglian bowl, found in Ormeside, Westmorland, England. 6. Gold ornament,

found in Knight's Field, Faversham, Kent. 7. The ring of Aethelwulf, father of Alfred the Great. Front and back views. 8. Frankish bronze ewer, probably 7th century, found at Wheathampstead. 9, 11. Anglo-Saxon gold brooches, designed in enamel and precious stones. 10. Gold staff head, from Cairnmuir, Peebleshire, Scotland

BY COURTESY OF (1, 3, 4, 7, 8, 12, 14, 15) THE TRUSTEES OF THE BRITISH MUSEUM, (2, 13, 16) THE DIRECTOR OF THE NATIONAL MUSEUM OF ANTIQUITIES, EDINBURGH, (5, 6, 9, 11) THE CURATOR OF THE COLCHESTER AND ESSEX MUSEUM, (10) THE CURATOR OF THE LETCHWORTH MUSEUM

### ARCHAEOLOGICAL SPECIMENS OF ANCIENT BRITISH ART

1. Bronze mirror, found at Disborough, Northamptonshire, probably 1st century. Decorative curves and basket-pattern filling are late Celtic. 2. Silver chain found at Crawfordjohn, Lanarkshire, dating probably from the period of Celtic Christianity. The chain is 18 in. long and on the penannular link, at the end, are incised symbols. 3. Bronze shield, ornamented in red enamel, found in the Thames, near Battersea, London. It is an example of late Celtic decoration. 4. Celtic helmets of bronze (early period). Left, helmet with enamelled ornaments found in the Thames near Waterloo bridge, London. Right, helmet found in a chariot-burial at Gorge-Millet, Somme Tourbe, Marne. 5. Leaden coffins. These specimens are now in the Colchester Museum. 6. Tombstone of Roman cavalry soldier, Colchester. The inscription reads "Longinus, son of Sdapezmatucus: duplicarius of the First Regiment of Thracian Cavalry; from the district of Sardica; aged 40; served 15 years. His heirs made this as directed by his will. He lies here." 7. Tiled tomb found at Old Windsor, dating from the Roman occupation of Britain. It contained an urn for ashes and

a small jar of red pottery. 8. Bronze spear-head, in use in Britain before iron was introduced. 9. Burial urns, examples of castor ware. The centre urn is the "Colchester Vase" with a representation of a gladiatorial display. 10. Roman pottery and glass. The group shows thirty-three vessels of the 1st and 2nd centuries, found in a cemetery at Baldock, Hertfordshire. 11. Roman pottery, Rhenish ware, decorated with white or yellow ornament, first imported towards the end of the 2nd century A.D. 12. Bronze vessel for temple use found at Prickwillow, Isle of Ely, bearing the name of the maker, Boduogenus, apparently a Briton. 13. Wrought-iron helmet with visor-mask, found at the Roman fort of Newstead, Melrose, originally encrusted with silver and used in tournaments. 14. Statuette of Osiris Pethempantes, found at Swanscombe, Kent, probably brought to England by the Romans. 15. Roman jug of pale olive-green glass, from a grave of Bayford-next-Sittingbourne, Kent, probably of 1st or 2nd century. 16. Brass helmet, found at the Roman fort of Newstead, Melrose. The embossed design shows a nude winged figure driving a leopard-drawn chariot

Ine, however, *pending*, *pen(n)ing* ("penny"), had already come into use for the latter, while, owing to the temporary disappearance of a gold coinage, *scilling* had come to denote a mere unit of account. It was, however, a variable unit, for the Kentish shilling contained 20 *sceattas* (pence), while the Mercian contained only four. The West Saxon shilling seems originally to have been identical with the Mercian, but later it contained five pence. Large payments were generally made by weight, 240-250 pence being reckoned to the pound, perhaps from the 7th century onwards. The mancus was equated with 30 pence, probably from the time of its introduction. This means that the value of gold relatively to silver was 10:1 from the end of Offa's reign. There is reason, however, for thinking that in earlier times it was as low as 6:1, or even 5:1. In Northumbria a totally different monetary system prevailed, the unit being the *tryms*, which contained three *sceattas* or pence. As to the value of the bronze coins we are without information.

The purchasing power of money was very great. The sheep was valued at a shilling in both Wessex and Mercia, from early times till the 11th century. One pound was the normal price of a slave and half a pound that of a horse. The price of a pig was twice, and that of an ox six times as great as that of a sheep.

**Ornaments.**—Of these the most interesting are the brooches which were worn by both sexes and of which large numbers have been found in heathen cemeteries. They may be classed under eight leading types: (1) circular or ring-shaped, (2) cruciform, (3) square-headed, (4) radiated, (5) S-shaped, (6) bird-shaped, (7) disk-shaped, (8) cupelliform or saucer-shaped. Of these Nos. 5 and 6 appear to be of Continental origin, and this is probably the case also with No. 4 and in part with No. 7. But the last-mentioned type varies greatly, from rude and almost plain disks of bronze to magnificent gold specimens studded with gems. No. 8 is believed to be peculiar to England and occurs chiefly in the southern Midlands, specimens being usually found in pairs. The interiors are gilt, often furnished with detachable plates and sometimes set with brilliants. The remaining types were probably brought over by the Anglo-Saxons at the time of the invasion.

Among other ornaments we may mention hairpins, rings and ear-rings, and especially buckles, which are often of elaborate workmanship. Bracelets and necklets are not very common, a fact which is rather surprising, as in early times, before the issuing of a coinage, these articles (*beagas*) took the place of money to a large extent. The glass vessels are finely made and of somewhat striking appearance, though they closely resemble contemporary Continental types. Since the art of glass-working was unknown, according to Bede, until nearly the end of the 7th century, it is probable that these were all of Continental or Roman-British origin.

**Amusements.**—It is clear from the frequent references to dogs and hawks in the charters that hunting and falconry were keenly pursued by the kings and their retinues. Games, whether indoor or outdoor, are much less frequently mentioned, but there is no doubt that the use of dice (*taefl*) was widespread. At court much time was given to poetic recitation, often accompanied by music, and accomplished poets received liberal rewards. The chief musical instrument was the harp (*hearpe*), which is often mentioned. Less frequently we hear of the flute (*pipe*) and later also of the fiddle (*fithle*). Trumpets (*horn*, *swegelhorn*, *byme*) appear to have been used chiefly as signals.

**Writing.**—The Runic alphabet seems to have been the only form of writing known to the Anglo-Saxons before the invasion of Britain, and indeed until the adoption of Christianity. In its earliest form, as it appears in inscriptions on various articles found in Schleswig and in Scandinavian countries, it consisted of 24 letters, all of which occur in abecedaria in England. In actual use, however, two letters soon became obsolete, but a number of others were added from time to time, some of which are found also on the Continent, while others are peculiar to certain parts of England. Originally the Runic alphabet seems to have been used for writing on wooden boards, though none of these has survived. The inscriptions which have come down to us are engraved partly on memorial stones, which are not uncommon in

the north of England, and partly on various metal objects, ranging from swords to brooches. The adoption of Christianity brought about the introduction of the Roman alphabet; but the older form of writing did not immediately pass out of use, for almost all the extant inscriptions date from the 7th or following centuries. Coins with Runic legends were issued at least until the middle of the 8th century, and some of the memorial stones date probably even from the 9th. The most important of the latter are the column at Bewcastle, Cumberland, believed to commemorate Alhfrith, the son of Oswio, who died about 670, and the cross at Ruthwell, Dumfriesshire, which is probably about a century later. The Roman alphabet was very soon applied to the purpose of writing the native language, e.g., in the publication of the laws of Aethelberht. Yet the type of character in which even the earliest surviving mss. are written is believed to be of Celtic origin. Most probably it was introduced by the Irish missionaries who evangelized the north of England, though Welsh influence is scarcely impossible. Eventually this alphabet was enlarged (probably before the end of the 7th century) by the inclusion of two Runic letters for *th* and *w*.

**Marriage.**—This is perhaps the subject on which our information is most inadequate. It is evident that the relationships which prohibited marriage were different from those recognized by the Church; but the only fact definitely known is that it was customary, at least in Kent, for a man to marry his stepmother. In the Kentish laws marriage is represented as hardly more than a matter of purchase; but whether this was the case in the other kingdoms also the evidence is insufficient to decide. It is known, however, that in addition to the sum paid to the bride's guardian, it was customary for the bridegroom to make a present (*morgengifu*) to the bride herself, which, in the case of queens, often consisted of a residence and considerable estates. Such persons also had retinues and fortified residences of their own. In the Kentish laws provision is made for widows to receive a proportionate share in their husbands' property.

**Funeral Rites.**—Both inhumation and cremation were practised in heathen times. The former seems to have prevailed everywhere; the latter, however, was much more common in the more northern counties than in the south, though cases are fairly numerous throughout the valley of the Thames. In *Beowulf* cremation is represented as the prevailing custom. There is no evidence that it was still practised when the Roman and Celtic missionaries arrived, but it is worth noting that according to the tradition given in the Anglo-Saxon Chronicle, Oxfordshire, where the custom seems to have been fairly common, was not conquered before the latter part of the 6th century. The burnt remains were generally, if not always, enclosed in urns and then buried. The urns are of clay, somewhat badly baked, and bear geometrical patterns applied with a punch. They vary considerably in size (from 4 to 12 in. or more in diameter) and closely resemble those found in northern Germany. Inhumation graves are sometimes richly furnished. The skeleton is laid out at full length, generally with the head towards the west or north, a spear at one side and a sword and shield obliquely across the middle. Valuable brooches and other ornaments are often found. In many other cases, however, the grave contained nothing except a small knife and a simple brooch or a few beads. Usually both classes of graves lie below the natural surface of the ground without any perceptible trace of a barrow.

**Religion.**—Here again the information is very limited. There can be little doubt that the heathen Angli worshipped certain gods, among them Ti (Tig), Woden, Thunor, and a goddess Frigg, from whom the names Tuesday, Wednesday, Thursday, and Friday are derived. Ti was probably the god to whom early Roman writers refer under the name Mars (see *TYR*), while Thunor was doubtless the thunder-god (see *THOR*). From Woden (*q.v.*) most of the royal families traced their descent. Seaxneat, the ancestor of the East Saxon dynasty, was also in all probability a god (see *ESSEX, KINGDOM OF*). Of anthropomorphic representations of the gods we have no clear evidence, though we do hear of shrines in sacred enclosures, at which sacrifices were offered. It is clear also that there were persons specially

set apart for the priesthood, who were not allowed to bear arms or to ride except on mares. Notices of sacred trees and groves, springs, stones, etc., are much more frequent than those referring to the gods. We hear also a good deal of witches and valkyries, and of charms and magic; as an instance may be cited the fact that certain (Runic) letters were credited, as in the North, with the power of loosening bonds. It is probable also that the belief in the spirit world and in a future life was of a somewhat similar kind to what is found in Scandinavian religion. (See TEUTONIC PEOPLES, 6.)

Reference must also be made to the articles on Anglo-Saxon antiquities in the *Victoria County Histories*, and to various papers in *Archaeologia* and other antiquarian journals.

(H. M. C.)

**BRITANNIA METAL**, a silvery white alloy with bluish tint, consisting essentially of tin and antimony, although copper is occasionally added. The best qualities of this alloy contain 90% of tin and 10% of antimony and may be regarded as tin hardened by antimony. Commoner grades of the alloy may contain 94% of tin, 5% of antimony and 1% of copper. The last mentioned metal increases the ductility and decreases the fusibility of britannia metal to which, however, it gives a yellowish tint. Britannia metal is employed in the manufacture of spoons, dish covers, tea pots and other hollow ware for table use. It is easily worked into complicated shapes by spinning or stamping and can then be silver plated. An increase in the proportion of antimony in the alloy raises the melting point, increases the hardness and diminishes the malleability.

A brilliant lustre is imparted to articles made from britannia metal by heating them for about 30 minutes in a bath containing water (120 parts), cream of tartar (12 parts), tartar emetic (one part), hydrochloric acid (16 parts), zinc (32 parts) and powdered antimony (8 parts). When the zinc of the foregoing bath is entirely replaced by antimony, warming for varying times produces diverse shades of bluish grey, copper red, gold and bluish or violet greys.

Britannia metal containing only tin and antimony is attacked but slightly by solutions of the chlorides of ammonium, magnesium, potassium and sodium, although aqueous caustic alkalis have a very appreciable corrosive action. (G. T. M.)

**BRITANNICUS**, son of the Roman emperor, Claudius, by Messalina, was born probably A.D. 41. He was originally called Claudius Tiberius Germanicus, and received the name Britannicus in honour of Claudius' expedition to Britain (A.D. 43). Till his mother's execution in 48 he was looked upon as the heir; but Agrippina, the new wife of Claudius, brought about the adoption of Nero, her own son by a former marriage. After the accession of Nero, Agrippina, by playing on his fears, induced him to poison

Britannicus at a banquet (A.D. 55). Britannicus is the subject of a tragedy by Racine.

See Tacitus, *Annals*, xii. 25, 41, xiii. 14-16; Suetonius, *Nero*, 33; Dio Cassius lx. 32, 34; see also works quoted under NERO.

**BRITISH CENTRAL AFRICA**, geographically the regions of central Africa in British possession, i.e., Nyasaland and Northern Rhodesia. In Feb. 1893 the Nyasaland Protectorate was officially styled "The British Central Africa Protectorate," but the old name was restored in Oct. 1907. (See NYASALAND PROTECTORATE and RHODESIA.)

**BRITISH COLUMBIA**, the western province of the Dominion of Canada. It is bounded on the east by the watershed in the Rocky Mountains until this, in its north-westerly course, reaches the meridian 120° W., which is followed north to 60° N., thus including within the province a part of the Peace river country east of the mountains. The southern boundary is formed by 49° N. and the straits separating Vancouver Island from the State of Washington. The northern boundary is 60° N., the western the Pacific ocean, upon which the province fronts for about 600m., and the coast strip of Alaska for a further 400m. Vancouver Island and the Queen Charlotte Islands, as well as the smaller islands lying off the western coast of Canada, belong to the province of British Columbia.

**Physical Features.**—British Columbia is almost wholly mountainous. It comprises nearly the whole width of the western mountain-belt of North America, between the parallels of latitude above indicated, including the Rocky Mountains proper on the east and the coast range on the west. Between these are other ranges to which various local names have been given, as well as the interior plateau—a hilly country, with summits having an accordant elevation east of the Coast Range. The several ranges, having been produced by foldings parallel to the border of the Pacific ocean, have a common trend S.E. to N.W. Vancouver Island and the Queen Charlotte Islands are parts of still another fold parallel to the coast, but largely submerged.

The Rocky mountains are composed chiefly of palaeozoic sediments from Cambrian to Carboniferous, with subordinate infolded areas of Cretaceous which hold coal. The average height of the range along the United States boundary is 8,000 ft., but the range culminates between the latitudes of 51° and 53°, in Mt. Robson, 13,068ft., and Mt. Alberta, in Alberta province, 13,500ft.; Mt. Fairweather in south Alaska is 15,287ft. Passes include the South Kootenay or Boundary pass, 7,100ft.; the Crow's Nest pass, 5,500ft. (this is traversed by the Canadian Pacific railway and crosses great coal fields); the Kicking Horse or Wapta pass, 5,300ft. (traversed by the main line of the Canadian Pacific railway); the Athabasca pass, 6,025ft.; the Yellow Head pass, 3,733ft. (used by the Canadian National railway); the Pine River pass, 2,850ft.; and the Peace River pass, 2,000ft., through which the Peace river flows.

The Coast or Cascade Range borders the Pacific coast for 900m., and its partially submerged transverse valleys give excellent harbours and deep sounds and inlets of extraordinary beauty. At the head of Knight Inlet, Lat. 51° 22' N., Long. 125° 16' W., Mt. George Dawson is the highest point in British Columbia (13,260ft.). The coast is fringed with innumerable islands, of which Vancouver Island and the Queen Charlotte Islands are the largest. Along the south-west side of the Rocky Mountains is a very remarkable valley of considerable geological antiquity, in which run some seven of the great rivers of the Pacific slope, among them the Kootenay, Columbia, Fraser and Finlay. This valley, 1 to 6m. wide, can be traced continuously for at least 800m. The Fraser, rising in the Rocky Mountains, flows for a long distance to the north-west and then, turning south, eventually crosses the Coast Range by a deep canyon and empties into the Strait of Georgia, a few miles south of the city of Vancouver. The Columbia, which rises farther south in the same range, flows north for about 150m. and then, bending abruptly back upon its former course, flows south through the Arrow Lakes in the Kootenay country into the United States, emptying into the Pacific ocean at Astoria in the state of Oregon. In the north-western part of the province the Skeena flows south-west into

the Pacific, and still farther to the north the Stikine rises in British Columbia, but before entering the Pacific crosses the coast strip of Alaska. The Liard, rising in the same district, flows eastwards and falls into the Mackenzie, which empties into the Arctic ocean. The headwaters of the Yukon are also situated in the northern part of the province. All these rivers are swift and frequently interrupted by rapids, so that, as means of communication, they are of little if any value; on the other hand there are in the province almost unlimited potentialities for water power.

At an early stage in the Glacial period British Columbia was covered by the Cordilleran ice-sheet, which moved south-east and north-west in correspondence with the ruling features of the country, from a gathering-ground about the 57th parallel. Ice poured through passes in the coast ranges, and to a lesser extent debouched upon the edge of the great plains, beyond the Rocky Mountain range. The great valley between the coast ranges and Vancouver island was also occupied by a glacier that moved in both directions from a central point in the vicinity of Valdez island. The effects of this glacial action have bearings on the distribution and character of the gold-bearing alluviums of the province.

**Climate.**—There are strong contrasts in respect both of rainfall and of temperature between the coast and the interior plateau, and, as regards rainfall on the coastlands, between places sheltered and unsheltered from wet westerly winds. Thus at Victoria, at the south end of Vancouver island, the mean annual rainfall amounts to 27.65in., but this place is sheltered by the heights of the island to the west. At Agassiz, on the narrow coastal plain of the Fraser river, the mean is 65.34in.: at both these stations the wettest months are in winter. At Kamloops in the south-central part of the province (1,193ft. above sea-level) the main annual rainfall is barely over 10in.; the maximum is in June, but in the later summer this division is definitely dry, with vegetation, except along the waterways and at the higher elevations, characteristic of an almost arid region. The mean monthly temperature ranges from 39°F. in January to 60° in July and August at Victoria, 34° in December to 69° in July at Agassiz, and 22° in January to 63° in July and August at Kamloops. At Atlin in the far north, eastward of the Coast Range, there is a mean temperature range from 0° in January to 54° in July; and a mean annual rainfall similar to that of Kamloops (10.89in.); on the other hand in the Prince Rupert and coastal district, the rainfall reaches 95in. or more.

**Fauna.**—Among the larger mammals are the big-horn or mountain sheep (*Ovis canadensis*), the Rocky Mountain goat (*Mazama montana*), the grizzly bear, moose, woodland caribou, black-tailed or mule deer, and coyote. All these are to be found only on the mainland. The black and brown bears, wolves, lynx, wapiti and Columbian or coast deer occur on both mainland and islands. About 340 species of birds are known in the province, including the burrowing owl of the dry interior, the American magpie, Steller's jay and a true nut-cracker, Clark's crow (*Picicorvus Columbianus*). True jays and orioles are also well represented. The gallinaceous birds include the large blue grouse of the coast, replaced in the Rocky Mountains by the dusky grouse. The western form of the spruce partridge of eastern Canada is also abundant, together with several forms referred to the genus *Bonasa*, generally known as partridges or ruffed grouse. Ptarmigan also abound in many of the higher mountain regions. Geese, brant and many sorts of duck are numerous.

**Area and Population.**—The area of British Columbia is 355,855sq.m. and its population by the census of 1931 was 694,263. The population roughly trebled in the first quarter of this century, at first by the influx of miners and others, consequent upon the discovery of precious metals in the Kootenay, Boundary and Atlin districts; and later by the establishment of a settled population through the opening up of the valleys by railways and motor roads, and new lines of steamboats, mainly in the south. The population is predominantly white. There is a considerable Chinese population, and 61,295 entered the country between 1921 and 1924. Chinese immigration has, however, been

forbidden by law since 1923, and was previously much reduced by the tax, rising in amount, imposed per head from 1885 onwards, owing to the objection felt by the white population to the entry of "Mongolians." Many Japanese have also come in: they are engaged chiefly in lumbering and fishing, and do not appear to be so much disliked as the Chinese, as they adapt themselves to the ways of white men, but they are equally objected to on the score of cheap labour; and in 1907-08 considerable friction occurred with the Dominion Government over the anti-Japanese attitude of British Columbia, which was shown in some rather serious riots. Since that time Japanese immigration has been restricted by agreement with the Japanese Government. In the census of 1921 the Indian population was returned at 22,377, largely Christian. The Indians are divided into very many tribes, but fall naturally on linguistic grounds into a few large groups. There is no treaty with the Indians of British Columbia, as with those of the plains, for the relinquishment of their title to the land, but the government otherwise assists them. There is an Indian superintendent at Victoria, and under him are agencies throughout the province to attend to the Indians—relieving their sick and destitute, supplying them with seed and implements, settling their disputes and administering justice. The Indian fishing stations and burial grounds are reserved, and other land has been set apart for them for agricultural and pastoral purposes. A number of schools have been established for their education. The chief cities are Victoria, the capital, on Vancouver Island; Vancouver and North Vancouver on the mainland, New Westminster on the Fraser and Nanaimo on Vancouver Island, Nelson in West Kootenay, Prince Rupert at the mouth of the Skeena river; Kamloops and Fernie in East Kootenay are also places of importance.

**Mining.**—Mining is one of the chief industries of British Columbia. The mining output has increased from \$4,225,717 in 1894 to \$67,718,400 in 1926. Gold was at first the most important mineral. Since 1899 placer mining has increased considerably, after a decline following the high production of the first few years, but the greater part of the return has been from lode mining. Rossland, Boundary and Kootenay districts are the chief centres of vein-mining yielding auriferous and cupriferous sulphide ores, as well as large quantities of silver-bearing lead ores. Gold has lately fallen to sixth place in annual value, the most valuable metals, in order of importance, being lead, copper, coal, zinc and silver. British Columbia has become the chief copper-producing state in Canada. The metal is worked largely in the coast districts, particularly on the Portland Canal (Anyox) and Howe Sound (Britannia), as well as in the inland areas already mentioned. Valuable discoveries of lead, silver and gold have been made in the coastal districts, and much gold and silver are produced near Stewart. There is also mining activity in the country behind Prince Rupert, and in recent years gold has again been recovered from the Cariboo and Cedar Creek areas where it was originally discovered. The mining laws are liberal, and, being based on the experience gained in the adjacent mining centres of the Western States, are convenient and effective. Among the most important smelting and reducing plants are those at Trail in the West Kootenay country, and at Anyox. There are also numerous concentrating plants. The province contains enormous supplies of excellent coal, largely untouched. It is chiefly of cretaceous age. The producing collieries are chiefly on Vancouver Island and on the western slope of the Rockies near the Crow's Nest pass. There are immense beds of high-grade bituminous coal and semi-anthracite in Northern British Columbia (Skeena Valley, etc.) and mining is developing along the line of the railway to Prince Rupert.

**Fisheries.**—A large percentage of the commerce is derived from the sea, the chief product being salmon. The halibut, herring and cod fisheries are also important, particularly the first, and whaling also is carried on. The chief centres of the salmon industry are the Fraser and Skeena rivers, Queen Charlotte Islands and Vancouver Island. There are several varieties of salmon, the chief being called sock-eyes, chums, pinks, cohoes and springs; the coarse chum salmon are salted for export to

the East. There are some 30 canning companies with 60 canning factories, employing largely Chinese labour, whilst many Japanese and Indians are engaged in the fisheries. Great Britain is the chief market for British Columbia salmon. Salmon hatcheries have been established on the chief rivers frequented by these fish. Large quantities of fish-oils are extracted from several species of dog-fish, whales, pilchards, etc.

**Timber.**—The province is rich in forests, and there is a steady demand for its lumber in the other parts of Canada, as well as abroad. Among the most important trees are Douglas fir, white and yellow pine, western hemlock, white spruce, Engellmann's spruce, giant cedar, yellow cypress or cedar and western larch. The principal timbers of commerce are the Douglas fir and the spruces; the former is often found 300ft. high and from 8 to 10ft. in diameter. The wood is tough and strong and is highly valued for ships' spars as well as for building purposes. White pine, hemlock and cedar are also much employed for various purposes. Owing to the scarcity of suitable streams for log-transport, the timber is conveyed mostly by special railways or motor tracks, and work is carried on all the year round.

**Manufactures.**—Manufacturing industries developed considerably during the World War and after. The bulk of the production is from saw-mills and pulp and paper factories, followed by fish curing and packing, electric light and power, and meat-packing. British Columbia possesses very large reserves of water-power on its numerous rivers and in recent years its exploitation has been begun by the erection of hydro-electric plants.

**Agriculture.**—Although mountainous in character, the province contains many tracts of good farming land. These lie in the long valleys between the mountain ranges of the interior, as well as on the lower slopes of the mountains and on the deltas of the rivers on Vancouver Island. Agriculture is now the most valuable industry of the country. Small mixed farming is predominant, and the chief crops raised are wheat, oats, clover, potatoes and other vegetables. Some areas are specially suited for cattle- and sheep-raising, among which may be mentioned the Yale district and the country round Kamloops. The breeding of fur-bearing animals is a growing industry. Much attention has been given to fruit-growing, particularly in the Okanagan valley. Apples, plums and cherries are grown as well as pears, peaches, apricots and various small fruits, notably strawberries. Hops are also cultivated. Beef, dairy produce (especially from the Lower Mainland) and honey are important products.

**Imports and Exports.**—For the year 1924-25 the total exports and imports were valued at \$147,531,000 and \$66,486,000. The chief exports are minerals, fish and fish products, lumber, grain, fruit, furs, etc.

**Railways.**—The Pacific division of the Canadian Pacific railway enters British Columbia through the Kicking Horse pass on the east and runs for about 500m. across the province before reaching the terminus at Vancouver, a line wonderfully engineered through some of the finest scenery in the Dominion. A branch of the same railway leaves the main line at Medicine Hat, and running to the south-west, crosses the Rocky Mountains through the Crow's Nest pass and thus enters British Columbia a short distance north of the United States boundary. This continues across the province, running approximately parallel to the boundary as far as Midway in what is known as the Boundary district. The line has opened up extensive coalfields and crosses a productive mining district. On Vancouver Island there are two railways, the Esquimalt and Nanaimo railway (78m.) connecting the coalfields with the southern ports, and the Victoria and Sydney railway, about 16m. in length. The Canadian National railway enters British Columbia over the Yellowhead pass, and follows the upper valley of the Fraser river and then that of the Skeena to Prince Rupert. A line also runs from the Yellowhead pass to Vancouver down the Thompson and Fraser valleys. There is also a number of short lines in the southern portion of the province connecting with lines in the United States. In 1926 there were 5,144m. of railway in the province.

**Shipping.**—The Canadian Pacific railway company has lines of steamers running from Vancouver and Victoria to (1) China

and Japan, (2) Honolulu, New Zealand and Australia, and also to Alaskan ports. Grand Trunk Pacific railway steamers run from Prince Rupert to Seattle, Vancouver, Victoria, Queen Charlotte Islands, Anyox, etc., and there are also boats to San Francisco and from Seattle to Northern Alaska (Nome).

**Government.**—The province is governed by a lieutenant-governor, appointed by the governor-general in council for five years, but subject to removal for cause, an executive council of five ministers, and a single legislative chamber. The executive council is appointed by the lieutenant-governor on the advice of the first minister, and retains office so long as it enjoys the support of a majority of the legislature. The powers of the lieutenant-governor in regard to the provincial government are analogous to those of the governor-general in respect of the Dominion government.

The British North America Act (1867) confederating colonies, defines the jurisdiction of the provincial legislature as distinguished from that of the Federal parliament, but within its own jurisdiction the province makes the laws for its own governance. The act of the legislature may be disallowed, within one year of its passage, by the governor-general in council, and is also subject to challenge as to its legality in the supreme court of Canada or on appeal to the juridical committee of the privy council of the United Kingdom. British Columbia sends six senators and 14 members to the lower house of the Federal parliament at Ottawa.

**Education.**—The educational system is under a department of education of the provincial government. The system includes day schools (97,954 pupils in 1925), vocational schools (9,704 pupils in 1925), Indian schools (2,736 pupils in 1925), the university of British Columbia (1,451 students in 1925), etc. The ordinary day-school has been free to pupils since 1872. The number of pupils receiving secondary education in 1924 was 4,380 boys and 5,509 girls. Vocational courses were introduced into high-school curricula in 1905 and the provincial university at Vancouver received its charter in 1908. Victoria has a College affiliated to the university and there are a Methodist College at New Westminster, an Anglican Theological College at Vancouver, and a Royal Naval College at Esquimalt.

**Finance.**—Under the terms of Union with Canada, British Columbia receives from the Dominion government annually a certain contribution, which has been \$738,816 for each year from 1921 to 1926. This, with provincial taxes on real property, personal property, income tax, sales of public land, timber dues, etc., brought the revenue in the year 1925 to \$18,823,358. The expenditure for the year (including sinking funds taken from capital expenditure) was \$20,156,702. The gross debt of the province in 1925 was \$91,640,679, with assets of \$85,420,187, or a net debt of \$6,220,492. These assets do not include new legislative buildings or other public works.

**History.**—The discovery of British Columbia was made by the Spaniard Perez in 1774. With Cook's visit the geographical exploration of the coast began in 1778. Vancouver, in 1792-1794, surveyed almost the entire coast of British Columbia with much of that to the north and south, for the British Government. The interior, about the same time, was entered by Mackenzie and traders of the North-West Company, which in 1821 became amalgamated with the Hudson's Bay Company. For the next 28 years the Hudson's Bay Company ruled this immense territory with beneficent despotism. In 1849 Vancouver Island was proclaimed a British colony. In 1858, consequent on the discovery of gold on the Fraser river and in the Cariboo district, and the large influx of miners, the mainland territory was erected into a colony under the name of British Columbia, and in 1866 this was united with the colony of Vancouver Island, under the same name. In 1871 British Columbia entered the confederation and became part of the Dominion of Canada. One of the conditions under which the colony entered the dominion was the speedy construction of the Canadian Pacific railway, and in 1876 the non-fulfilment of this promise created strained relations. This was ameliorated when the construction of the road was begun. (See F. B. Thornhill, *British Columbia in the Making* (1913); H. Howard, *The Glamour of British Columbia* (1926).)

**BRITISH COTTON AND WOOL DYERS ASSOCIATION, LTD.** This is the largest combination of yarn dyers in the world. Its chief business is to dye yarn or other raw material previous to its actual manufacture into cloth by the weaver or into web by the knitter. Thus, for the cotton spinner the company dyes raw cotton, while for the cotton manufacturer cotton yarn is dyed, printed, bleached or sized. For the worsted spinner wool is dyed, while for the woollen or worsted manufacturer yarns are dyed, printed or bleached. The rise of the artificial silk industry increased the range of the combine's operations. For another important industry, hosiery, it dyes or prints or bleaches the appropriate yarns, delivering them ready for use in hank or on bobbin. Some of the branches do special work in dyeing yarns for the peculiar requirements of various oversea markets. The mercerizing of yarns is another department of importance.

The company's special interest in yarn as one of their chief raw materials leads them to act as yarn merchants; carrying large stocks they can expedite the delivery of finished dyed products. So the association becomes a great self-contained business, which in addition to dyeing operates large warping, beaming and winding plants to enable it to serve all classes and all markets at home and abroad. That is its main business, but in addition it operates a large cotton cloth dyehouse and finishing works, a department for the dry-cleaning and dyeing of garments, and a chemical works and dyewood grinding factory.

The company was floated early in 1900, to acquire and amalgamate 46 English and Scottish companies and firms. Additional works were afterwards acquired. The authorized capital in 1927 was 4,000,000 shares of 5/- each, of which 3,096,660 fully paid had been issued, amounting to £774,165. There was also an authorized 4% First Mortgage Debenture Stock of £750,000, of which £620,000 had been issued. At March 31 1927, the capital value of the operating works stood at £1,554,024. The central office is at Manchester.

The economies of an association of this character are manifold, whether in the centralized purchase of supplies, in finance, or in the organization of selling. Not the least valuable feature has been the gradual equipment of specific branches for certain types of trade or work. The company has central laboratories for investigation and research into the chemical and engineering problems of the textile industries, and is able to maintain a very high standard of personnel and equipment.

The company maintains a welfare department and provides canteens and rest rooms, and has established an employees' insurance scheme, which, without contribution from the employees, provides liberal sums varying from £100 upwards for the dependents of any worker who dies whilst in the company's employ. (L. C. M.)

#### **BRITISH DYESTUFFS CORPORATION, LIMITED.**

The first Aniline Dye was discovered by William Henry Perkin in 1856, during an attempt to produce quinine. He proceeded to erect a works near London, and, towards the end of 1857, the first synthetic dye was being manufactured. The discovery opened out an illimitable field for invention, and within a few years the industry which Perkin started was destined to kill the extensive French madder trade, and, later, to reduce the centuries-old Indian indigo plantations to unimportant dimensions. It paved the way for the science of chemical therapeutics and led to the development of synthetic drugs. The practical performance of Perkin's discovery was made possible by the work of two other Englishmen—Faraday, who discovered benzene in 1825, and Mansfield, who carried out its actual separation from coal tar on an industrial scale in 1827.

The British Dyestuffs Corporation thus has a two-fold connection with this discovery, for Mansfield founded what is still the Turnbridge Works of the corporation, and, through Claus & Co., it can trace its descent from Perkin & Sons.

For a brief period, the infant industry established by Perkin's discovery developed in England. The manufacture of aniline was taken up by Simpson, Maule & Nicholson, and to this firm we owe the first soluble blues and the beginning of the great range of azo dyestuffs. Read, Holliday of Huddersfield was founded in

1860, and Levinstein, Ltd. of Manchester, in 1865. Brooke, Simpson & Spiller, founded in 1868, acquired Perkin's firm in 1874, ultimately selling its own goodwill to Claus & Rée, in 1906, which firm in turn, was purchased by Levinstein in 1917.

After the first brilliant efforts, research in England languished; the older men associated with the early period of development fell out, and no new school of leaders was available to take their place. In the meantime, other countries seized upon the new discoveries. By 1885, the British dyestuffs industry had lost the greater part of its trade, and Germany became the chief supplier of synthetic dyestuffs to the whole world.

On the outbreak of war in 1914, the colour-consuming trades found themselves cut off from what had become the chief source of supply. A representative meeting of British dye consumers was held at the Board of Trade in Dec. 1914. Following the recommendations of this committee, a company called "British Dyes, Limited" was incorporated in 1915, and a prospectus issued inviting subscriptions for £1,000,000 capital from the colour-using industries. The government agreed, under certain conditions, to advance a sum not exceeding £1,500,000.

It was upon the efforts of this company and of Levinstein, Ltd., that the colour users were very largely dependent for their supplies of dyestuffs during the period of the War.

Towards the end of 1918, it was felt that the rate of progress was not satisfactory, and it was finally determined that this object could better be secured by effecting a fusion of interests of British Dyes, Ltd. and Levinstein, Ltd. British Dyestuffs Corporation, Ltd. was incorporated for this purpose, and a prospectus was issued inviting subscriptions for £5,000,000 of new capital. In consideration of their financial support, the British Government stipulated for the nomination of two Directors and for certain powers of veto and control.

The corporation was faced with the problems of peace, which were far more exacting than those of war. The situation was complicated by the free importation of dyestuffs in the interval between the Sankey Judgment and the passing into law of the Dyestuffs (Import Regulation) Act and by the very serious trade depression. In Dec. 1925, the Government agreed to terminate its powers and to surrender its shareholding in return for a payment of £600,000, and under a scheme of reconstruction, the issued capital was reduced from £9,197,000 to £4,775,000. In 1926, the British Dyestuffs Corporation became a constituent unit of Imperial Chemical Industries, Ltd.

The corporation owns extensive works at Huddersfield, Manchester and Ellesmere Port; in these works is performed the manufacture from coal tar of the primaries, such as aniline, of dyestuff intermediates and, finally, of a complete range of the finished dyes of every class.

The dyestuffs industry is one for the trained chemist. Research, which, it is agreed, is vital, is now carried out on a scale entirely unprecedented in Britain, but research is not all; laboratory experiment is often very different from the large-scale manufacture and, here, comes in technical ability. The corporation operates a particularly complete small-scale plant on which the technical aspect of works operations can be studied. Equally practical are the laboratories attached to the Dyehouse and the Service Departments, in which colours are standardized and the needs of customers studied. The industry is the nucleus of the synthetic organic industry, and its highly trained staff of chemists, technicians and engineers is available for the establishment of the manifold new industries connected with organic chemistry which to-day are coming into prominence. (E. F. AR.)

**BRITISH EAST AFRICA**, in its narrower sense the name by which the East Africa Protectorate was generally known until in 1920 it became Kenya Colony and Protectorate (*see* KENYA COLONY). In its wider sense the term includes all the territories in East Central Africa under British administration, namely Uganda, Kenya, Tanganyika, Zanzibar, Nyasaland and Northern Rhodesia.

Since Tanganyika Territory (formerly German East Africa) came in 1919 under a British mandate these regions form a continuous block of country extending from the Zambezi to the

Upper Nile. Their common interests led to co-operation in various economic spheres, and to a movement for political union or federation. The position in East Africa as a whole was studied on the spot by a parliamentary commission in 1924; in 1926 a conference was held in Nairobi of the governors of all the territories concerned, and in 1928 a commission appointed by the British Government further studied the question of federation. But unanimity of opinion on the subject was lacking. In Zanzibar, where connections are mainly with India, federation was frankly opposed, while the white settlers in Northern Rhodesia were divided in their view as to whether their future lay with South or East Africa. As for Tanganyika, fears were expressed that there was something temporary and uncertain in the British tenure of that territory under the mandate. On this point the secretary for the colonies, Mr. L. Amery, declared, June 11, 1926, that Great Britain held Tanganyika in her own right under the Treaty of Versailles, and that the foundations of the East Africa of the future were as sure and permanent in Tanganyika as they were in any other East African territory. The most ardent advocates of federation were the white settlers in Kenya. Their leader, Lord Delamere (the 3rd baron), presided over conferences of unofficial delegates to further joint action, held at Tukuyu (in Tanganyika) in 1925 and at Nairobi in 1927. The general view, in 1928, was that should closer union be deemed desirable the first step should be a federation of Uganda, Kenya and Tanganyika.

The *Report of the East Africa Commission* (Cmd. No. 2387) (H.M. Stationery Office, 1925) summarizes the position and needs of East Africa; Major A. Church, in *East Africa: A New Dominion* (1927), deals largely with native interests. See also *Future Policy in regard to East Africa* (Cmd. 2904) (1927) and authorities cited under KENYA; TANGANYIKA, etc.

#### DEFENCE

British responsibilities for defence in East Africa have been widely extended by the acceptance of "mandates" after the World War. The King's African Rifles, whose history dates from 1891, is the main defensive force in East Africa. The K.A.R. is a regular regiment, with native personnel drawn from numerous tribes, under officers seconded from the British army. In 1918 there were 22 battalions with over 38,000 enrolled. There are now five battalions and a camel corps (Somaliland). Two battalions are in Nyasaland, one in Kenya Colony, one in Uganda and one in Tanganyika Territory. The troops in each of these territories (see also GREAT BRITAIN, *Colonial Forces*) are under the orders of the Governor. Administration and training is superintended by an inspector general, under the Colonial Office, with headquarters in London. Enlistment is for six years, with re-engagements for three years, up to 18 years' service. Reserves may be called up on permanent service or in aid of civil power, or for 31 days' training in any one year. The force is liable to service in any part of the world. There are also police forces for local service. The total peace strength of the K.A.R. is about 5,700.

See also League of Nations, *Armaments Year-Book* (1928); *Notes on the Land Forces of British Dominions, Colonies and Protectorates* (British War Office, Dec. 1925), and *Annual Army Estimates*.

**BRITISH ELECTRICAL MANUFACTURERS' ASSOCIATION.** In administration two main principles have governed the development of the electrical industry in Great

Britain—large-scale production and co-operation of manufacturers within a central trade association. Both principles are closely related, since effective co-operation can only take place in an industry when a certain degree of concentration has been effected between manufacturers. Thus, in British electrical engineering proper, four large firms with an annual output exceeding £28 millions, and, in cable manufacture, six firms with an annual output exceeding £15 millions, have dominated the course of expansion and, in a great measure, determined the organization of the entire electrical industry. These ten firms are responsible for 60% of the British production.

In electrical and allied engineering, which includes steam turbines, boilers, condensing plant and other mechanical engineering products required for the equipment of generating stations, the British Electrical and Allied Manufacturers' Association represents the producers, while the Cable Makers' Association deals with cables and the Electric Lamp Manufacturers' Association with lamps.

Of these associations, the first named is much the most important, since it includes practically all the members of the other two and generally acts on behalf of the entire industry. It was formed in 1911 and now covers through its 184 members about 85% of the national production in all lines of electrical manufacture. It was formed with a view to creating: (1) A central organization for the discussion and treatment of all questions affecting the electrical industries; (2) a medium of communication between the manufacturers and the Government and local authorities; (3) an organ for promoting trade in overseas markets; and (4) an economic and technical intelligence service.

In all these directions its work has been of distinct value to the industry as in connection with the Electricity Supply Act of 1926. It finances research carried out by the British Electrical and Allied Industries Research Association, and electrical propaganda and educative work carried out by the British Electrical Development Association, and has promoted standardization through the British Engineering Standards Association and the International Electro-Technical Commission.

Recent developments of significance have lain in the formation of the World Power Conference International Committee, arising out of the First World Power Conference of 1924. This organization carried out in the international field functions similar to those already performed by the British Electrical and Allied Manufacturers' Association.

The Association has extended its economic and statistical services, issues quarterly a trade survey giving essential statistics for the leading industrial countries, and from time to time special studies of electrical development, including "Combines and Trusts in the Electrical Industry," "The Electrical Industry in Germany," "The Electrical Industry in France," and the "Monograph on the Electrical Industry" submitted to the International Economic Conference.

Within the Association itself a number of groups deal with special lines of manufacture, such as steam turbines, generating plant, electric motors, transformers, switchgear, meters and instruments and domestic apparatus. Within them, the manufacturers are able to discuss conditions and co-ordinate policy without, however, exerting direct control over production on the German model. They are largely advisory in nature and co-operate to eliminate uneconomic conditions of contract and of price. (H. Q.)

**BRITISH EMPIRE**, the name given to the whole aggregate of territory, the inhabitants of which, under various forms of government, are linked together by a common ultimate allegiance to the British Crown as their titular sovereign.

#### I. AREA AND POPULATION

The land surface of the earth is estimated to extend over about 52,500,000 square miles. Of this area the British empire occupies nearly one-quarter, or about 12,000,000 square miles. By far the greater portion lies within the temperate zones, and is suitable for white settlement. The notable exceptions are the southern half of India and Burma; East, West and Central Africa; the West

BY COURTESY OF F. B. PATTERSON

NATIVE AMID THE GRASS OF THE PLAINS IN BRITISH EAST AFRICA

BY COURTESY OF THE PHELPS STOKES FUND

YOUNG WOMAN CARRYING WATER IN NATIVE FASHION

Indian colonies; the northern portion of Australia; New Guinea, British Borneo and that portion of North America which extends into Arctic regions. The area of the territory of the empire is divided almost equally between the southern and the northern hemispheres, the great divisions of Australasia and South Africa covering between them in the southern hemisphere 5,308,506 sq.m., while Great Britain and Ireland, Canada and India, including the native States, cover between them in the northern hemisphere 5,271,375 square miles. The alternation of the seasons is thus complete, one half of the empire enjoying summer, while one-half is in winter. The division of territory between the eastern and western hemispheres is less equal, Canada occupying alone in the western hemisphere 3,653,946 sq.m., while Australasia, South Africa, India and Great Britain and Ireland occupy in the eastern hemisphere 6,925,975 square miles. As a matter of fact, however, the eastern portions of Australasia border so nearly upon the western hemisphere that the distribution of day and night throughout the empire is, like the alternations of the seasons, almost complete, one-half enjoying daylight, while the other half is in darkness. These alternations of time and of seasons, combined with the variety of soils and climates, are calculated to have an increasingly important effect upon the material and industrial, as well as upon the social and political developments of the empire. According to the latest census reports and estimates available in 1927, the total population of the empire is over 445,000,000. Its white population, which includes some French, Dutch and Spanish peoples, but is mainly of Anglo-Saxon race, numbers over 66,000,000. It is distributed roughly as follows:—

|  |                  |
|--|------------------|
| Great Britain and Northern Ireland . . . . .           | 44,200,000       |
| Irish Free State . . . . .                             | 3,165,000        |
| Australasia . . . . .                                  | 7,388,000        |
| Canada and Newfoundland . . . . .                      | 9,763,000        |
| South Africa . . . . .                                 | 1,672,000        |
| India . . . . .  | 115,000          |
| West Indies and various other colonies (say) . . . . . | 120,000          |
|  | <hr/> 66,423,000 |

The native population of the empire includes types of the principal black, yellow and brown races, classing with these the high-type races of the East, which may almost be called white. The native population of India, mainly high type, brown, was returned at the census of 1921 as 318,338,954. The population of India is divided into 118 groups on the basis of language. These may, however, for the sake of convenience, be collected into the following principal groups:—

- (A) Malayo-Polynesian.
- (B) Indo-Chinese.
  - i. Mon-Khmer.
  - ii. Tibeto-Burman.
  - iii. Siamese-Chinese.
- (C) Dravido-Mundā.
  - i. Mundā (Kolarian).
  - ii. Dravidian.
- (D) Indo-European.
  - Indo-Aryan sub-family.
- (E) Semitic.
- (F) Hamitic.
- (G) Unclassed, e.g., Gypsy.

#### Eastern Colonies

|                          |                 |
|--------------------------|-----------------|
| Ceylon . . . . .         | 4,496,450*      |
| British Malaya . . . . . | 968,332†        |
| Hongkong . . . . .       | 857,920†        |
| Borneo . . . . .         | 883,180*†       |
|                          | <hr/> 7,205,882 |

\*Census, 1921. †Estimate, 1925.

FIG. 1.—DIAGRAM SHOWING WORLD DISTRIBUTION OF THE 450 MILLION INHABITANTS OF THE BRITISH EMPIRE

The native population of Ceylon is mainly high type brown (about 3,000,000 Sinhalese and over 1,000,000 Tamils). In British Malaya and Borneo the natives are Malay, but Chinese immigrants have settled there in almost equal numbers. The population of Hongkong is virtually Chinese, the inhabitants of other races only numbering about 16,000.

#### West Indies

The West Indies, including the continental colonies of British Guiana and Honduras, and 17 islands or groups of islands, have a total coloured population of about 2,045,000. The colonies of this group which have the largest coloured populations are:—

|  |                  |
|--|------------------|
| Jamaica—chiefly black, some brown and yellow . . . . . | 900,000          |
| Trinidad and Tobago—black and brown . . . . .          | 380,000          |
| British Guiana—black and brown . . . . .               | 304,000          |
|  | <hr/> 1,584,000† |

†Estimate 1925.

The populations of the West Indies are very various, being made up largely of the descendants of imported African negro slaves. In Jamaica these contribute four-fifths of the population. There are also in the islands a considerable number of imported East Indian coolies and some Chinese. The aboriginal races include American Indians of the mainland and Caribs. With these there has been intermixture of Spanish and Portuguese blood, and many mixed types have appeared. The total European population of this group of colonies amounts to upwards of 90,000, to which 13,000 on account of Bermuda may be added.

#### South Africa

|  |                  |
|--|------------------|

| Bantu . . . . .                                  | 1,140,642†       |
| D. <i>Southern Rhodesia</i>                      |                  |
| Bantu . . . . .                                  | 834,473†         |

\*Census, 1921. †Estimate, 1925.

The aboriginal races of South Africa were the Bushmen and Hottentots. Both these races are rapidly diminishing in numbers; the Bushmen are nearly extinct; and though the Hottentot strain is preserved in the half-castes or "coloured people," the pure stock is also dying out. Besides these primitive races there are the dark-skinned negroids of Bantu stock, commonly known in their tribal groups as Kaffirs, Zulu, Bechuana and Damara, which are again subdivided into many lesser groups. There are also in the Union, Malays, Indians and others, who during the last 200 years have been introduced from Java, Ceylon, Madagascar, Mozambique and British India, originally as slaves and in the 19th century as indentured labourers, when they were used mainly for the sugar plantations of Natal.

#### East Africa

\*Census, 1921. †Estimate, 1925.

From east to west across Africa the aboriginal nations are mostly of the black negroid type. The tendency of some of the lower types has been to drift towards the west coast, where they still practise cannibalistic and fetish rites. On the east coast are found much higher types approaching to the Christian races of Abyssinia, and from east to west there has been a wide admixture of Arab

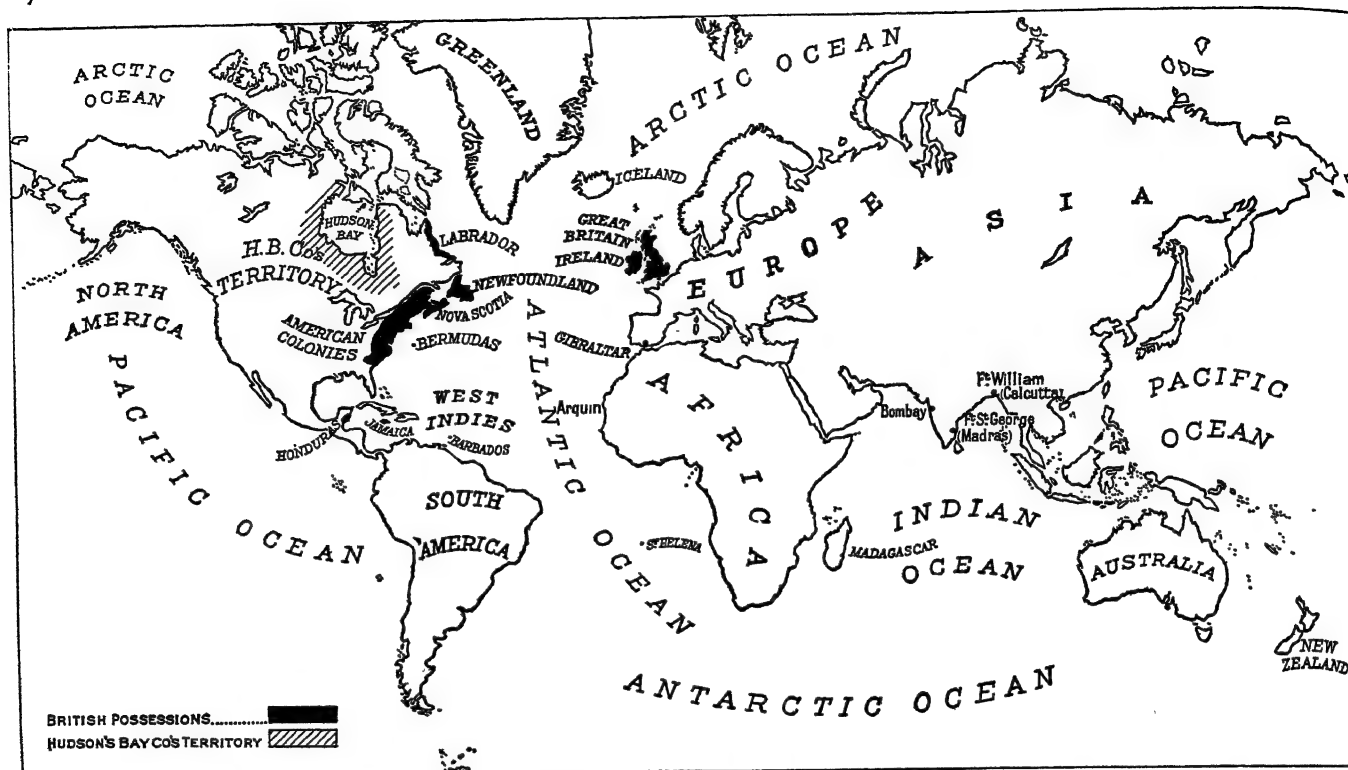

FIG. 2.—MAP OF THE BRITISH EMPIRE IN 1714, SHOWING (IN BLACK) BRITISH POSSESSIONS OF THAT TIME. THE HUDSON'S BAY COMPANY, HOLDING SPECIAL TRADING RIGHTS, WERE NOMINAL RULERS IN THE NAME OF THE BRITISH SOVEREIGN, OVER THE TERRITORY (SHADED) ROUND HUDSON BAY

blood producing a light-brown type. In Uganda and Nigeria a large proportion of the population is Arab and relatively light-skinned.

#### Australasia

| Papua—Polynesian, black and brown           | 275,000  |
|   | 607,268  |

\*Census, 1921. \*\*Census, 1926.

The aboriginal tribes of Australia are of a primitive pre-Dravidian black race. The natives of the islands east of Fiji are Malayo-Polynesians, tall, handsome and light-brown in colour. Their highest and lightest type is represented by the Maoris of New Zealand. In the islands west of Fiji the natives are Melanesians, a darker and lower type, ranging from black to brown. The Fijians are a mixture of the two. The original natives of Papua are primitive and sometimes cannibals, but there is a substantial immigrant Melanesian stock. The estimate given for Papua is approximate, as no census has been taken.

#### Canada

|               |         |

#### Summary

|                             |             |
|-----------------------------|-------------|
| Native populations:         |             |
| India                       | 318,338,954 |
| Ceylon and Eastern Colonies | 7,205,882   |
| West Indies                 | 1,584,000   |
| South Africa                | 8,141,987   |
| East Africa                 | 13,629,274  |
| West Africa                 | 21,887,491  |
| Australasia and Islands     | 607,268     |
| Canada                      | 166,269     |
|                             | 371,561,125 |
| White populations           | 66,423,000  |
| Total                       | 437,984,125 |

This is without taking into account the population of the lesser Crown colonies or allowing for the increase likely to be shown by later censuses. The population of the earth as a whole can only be estimated loosely; but the population of the empire probably constitutes at least a quarter of it.

## II. GROWTH OF THE EMPIRE

It is a matter of first importance in the geographical distribution of the empire that the five principal divisions, the British Isles, South Africa, India, Australia and Canada are separated from each other by the three great oceans of the world. The distance, as usually calculated in nautical miles, from England to the Cape of Good Hope is 5,840m.; from the Cape of Good Hope to Bombay is 4,610m.; from Bombay to Melbourne is 5,630m.; from Melbourne to Auckland is 1,830m.; from Auckland to Vancouver is 6,210m.; from Halifax to Liverpool is 2,744 miles. From a British port direct to Bombay by way of the Mediterranean it is 6,272m.; from a British port by the same route to Sydney 11,548 miles. These great distances have necessitated the acquisition of intermediate ports suitable for coaling stations on the trade routes, and have determined the position of many of the lesser Crown colonies which are held simply for military and commercial purposes. Such are the Bermudas, Gibraltar, Malta, Aden, Ceylon, the Straits Settlements, Labuan, Hongkong, which complete the chain of connection on the eastern route and such on other routes are the lesser West African stations, Ascension, St. Helena, the Mauritius and Seychelles, the Falklands, Tristan da Cunha and the groups of the western Pacific. Other annexations of the British empire have been rocky islets of the northern Pacific required for the purpose of telegraph stations in connection with an all-British cable.

The spread of the empire over the oceans of the world is a matter of relatively modern history. The Channel Islands became British as a part of the Norman inheritance of William the Conqueror. The Isle of Man, which was for a short time held in conquest by Edward I. and restored, was sold by its titular sovereign to Sir William Scrope, earl of Wiltshire, in 1393, and by his subsequent attainder for high treason and the confiscation of his

estates, became a fief of the English Crown. It was granted by Henry IV. in 1406 to Sir John Stanley, K.C., ancestor of the earls of Derby, by whom it was held till 1736, when it passed to James Murray, 2nd duke of Atholl, as heir-general of the 10th earl. It was inherited by his daughter Charlotte, wife of the 3rd duke of Atholl, who sold it to the Crown for £70,000 and an annuity of £2,000. With these exceptions and the nominal possession taken of Newfoundland by Sir Humphrey Gilbert in 1583, all the territorial acquisitions of the empire have been made since 1600.

The following is a list of the British colonies and dependencies (other than those belonging to the Indian empire) together with a summary statement of the date and method of their acquisition. Arranged in chronological order they give some idea of the rate of growth of the empire. The dates are not, however, in all cases those in which British sovereignty was established. They indicate in some instances only the first definite step, such as the building of a fort, the opening of a trading station, or other act, which led later to the incorporation in the empire of the country indicated. In the case of Australian States or Canadian provinces originally part of other States or provinces the date is that, approximately, of the first settlement of British in the district named; e.g., there were British colonists in Saskatchewan long before it was constituted a province in 1905. Save where otherwise stated, British authority has been continuous from the first date mentioned in the table. Reference should be made to the articles on the various colonies.

| Name.         | Date. | Method of Acquisition.                            |
|---------------|-------|---|
| Newfoundland. | 1583  | Possession taken by Sir H. Gilbert for the Crown. |

## 17th Century.

|                                      |         |  |
|--------------------------------------|---------|--|
| Barbados . . . .                     | 1605-25 | Settlement.  |
| Bermudas . . . .                     | 1609    | "  |
| Gambia . . . . .                     | c.1618  | " A second time in 1816.   |
| St. Christopher. . . .               | 1623    | " Did not become wholly British until 1713.  |
| Nova Scotia . . . .                  | 1628    | " Ceded to France 1632; recovered 1713.  |
| Nevis . . . . .                      | 1628    | "  |
| Montserrat . . . .                   | 1632    | "  |
| Antigua . . . . .                    | 1632    | "  |
| Honduras . . . . .                   | 1638    | "  |
| St. Lucia . . . . .                  | 1638    | " Finally passed to Great Britain in 1803.   |
| Gold Coast . . . .                   | c.1650  | Settlement. Danish forts bought 1850, Dutch forts 1871. Northern territories added 1897.                           |
| St. Helena. . . . .                  | 1651    | Settled by East India Co. Government vested in British Crown 1833.   |
| Jamaica . . . . .                    | 1655    | Conquest.  |
| Bahamas . . . . .                    | 1666    | Settlement.  |
| Virgin Islands . . . .               | 1666-72 | Settlement and conquest.   |
| N.W. Territories of Canada . . . . . | 1669    | Settlement under royal charter of Hudson's Bay Co. Purchased from Imp. Gov. 1869, and transferred to Canada 1870.. |
| Turks and Caicos Is. . .             | 1678    | Settlement.  |

## 18th Century.

|                         |      |                         |
|-------------------------|------|-------------------------|
| Gibraltar . . . . .     | 1704 | Capitulation.           |
| Prince Edward Is. . . . | 1758 | Conquest. 1763 Cession. |
| Ontario } . . . . .     | 1759 | Conquest. 1763 Cession. |
| Quebec }                |      |                         |

These names first adopted when the single Province of Canada was divided to form with New Brunswick and Nova Scotia the Dominion of Canada 1867. Prince Edward Is. entered the confederation 1873. In 1880 all British possessions (other than Newfoundland) in North America annexed to the Dominion.

| Transvaal and Swaziland . . . . .                 | 1900    | Annexation. Formerly British 1877-81.   |
| 20th Century.                                     |         |   |
| Kelantan, Trengganu, etc. . . . .                 | 1909    | Cession from Siam.  |

In the Pacific are also Bird Island, Bramble Cay, Cato Island, Cook Islands, Danger Islands, Ducie Island, Dudosia, Howland Island, Jarvis Island, Kermadec Islands, Macquarie Island, Manihiki Islands, Nassau Island, Palmerston Island, Palmyra Island, Phoenix group, Purdy group, Raine Island, Rakaanga Island, Rotumah Island, Surprise Island, Washington or New York Island, Willis group and Wreck reef.

In the Indian ocean there are, besides the colonies already mentioned, Rodriguez, the Chagos Islands, St. Brandon Islands, Amirante Islands, Aldabra, Kuria Muria Islands, Maldive Islands and some other small groups.

The Indian section of the empire was acquired during the 17th-19th centuries under a royal charter granted to the East India Company by Queen Elizabeth in 1600. It was transferred to the Imperial Government in 1858, and Queen Victoria was proclaimed empress under the Royal Titles Act in 1877. The following list gives the dates and method of acquisition of the centres of the main divisions of the Indian empire. They have, in most instances, grown by general process of extension to their present dimensions.

| Name.                                       | Date.        | Method of Acquisition.   |
|---|--------------|--|
| Madras . . . . .                            | 1639 to 1748 | By treaty and subsequent conquest. Fort St. George, the foundation of Madras, was the first territorial possession of the E.I. Co. in India. It was acquired by treaty with its Indian ruler. Madras was raised into a presidency in 1683; ceded to France 1746; recovered 1748. |
| Bombay . . . . .                            | 1608 to 1685 | Treaty and cession. Trade first established 1608. Ceded to British Crown by Portugal 1661. Transferred to E.I. Co. 1668. Presidency removed from Surat 1687.   |
| Bengal . . . . .                            | 1633 to 1765 | Treaty and subsequent conquests. First trade settlement established by treaty at Pipili in Orissa 1633. Erected into presidency by separation from Madras 1681. Virtual sovereignty announced by E.I. Co. as result of conquests of Clive, 1765.                                 |
| Behar and Orissa . . . . .                  |              | Detached from Bengal as separate province under lieut.-governor 1912, under governor 1919.   |
| United Provinces of Agra and Oudh . . . . . | 1764 to 1856 | By conquests and treaty through successive stages, of which the principal dates were 1801-03-14-15. In 1832 the nominal sovereignty of Delhi, till then retained by the Great Mogul, was resigned into the hands of E.I. Co. Oudh was finally annexed in 1856.                   |

| Name.                             | Date.   | Method of Acquisition.  |
|-----------------------------------|---------|---|
| Central Provinces . . . . .       | 1802-17 | By conquest and treaty.   |
| Assam . . . . .                   | 1826-39 | Conquest and cession. First annexed to Bengal. Detached as separate chief commissionership 1874. United with Eastern Bengal 1905. Again detached 1912. Made a governor's province 1921. |
| Burma . . . . .                   | 1824-52 | Conquest and cession.   |
| Punjab . . . . .                  | 1849    | Conquest and annexation. Made into distinct province 1859.  |
| N.-W. Frontier Province . . . . . | 1901    | Subdivision.  |
| Delhi . . . . .                   | 1912    | Detached from Punjab as distinct small province under chief commissioner.   |
| Ajmere and Merwara . . . . .      | 1818    | By conquest and cession.  |
| Coorg . . . . .                   | 1834    | Conquest and annexation.  |
| British Baluchistan . . . . .     | 1854-76 | Conquest and treaty.  |
| Andaman Islands . . . . .         | 1858    | Annexation.   |

The above territories constitute British India. The rest of the sub-continent is made up of so-called native States, numbering over 500, of greatly varying sizes situated in various parts of India, and containing in all a population of nearly 72,000,000. These States are governed by their own princes or chiefs, the more important of whom are autonomous in their domestic affairs, but, under treaties, they all owe allegiance to the King-Emperor and their external relations are under the control of the governor-general in council. Nepal stands alone as a wholly independent kingdom—a status confirmed by the treaty of 1923; but, since the war of 1814-15, it has maintained close and friendly relations with the British Government and a British envoy resides according to treaty at the capital. Between the north-west frontier of British India and that of Afghanistan there are districts known as the North-West Frontier Agencies and Tribal Areas, over which the Government of India exercises surveillance but interferes as little as possible with the rule of the tribal chiefs.

### III. POLITICAL DEVELOPMENT

This vast congeries of communities, widely varying in character and absorbed within the empire by varying methods, is governed, under the supreme headship of the British Crown, in several different forms. These forms of government are the outcome of a process of development which is continually at work and has not yet reached its final stages.

The empire may be divided into the following political classes:—

(1) The United Kingdom of Great Britain and Ireland, consisting of England, Wales, Scotland and Northern Ireland. It possesses full sovereignty, external and internal, but is limited in action as regards the dominions by certain recognized conventions. Northern Ireland has a parliament and a Government responsible to it for local matters. The Channel Islands and the Isle of Man, are in an anomalous position inasmuch as they have independent legislatures and semi-independent executives, subject to the supremacy of the British parliament.

(2) The self-governing dominions, possessing membership in the League of Nations and therefore a quasi-international status, and, though *de jure* still subject to the supremacy of the British parliament, possessing *de facto* the same independent status as Great Britain with which they are equal members of the Imperial Conference. These are Canada, Australia, New Zealand, South Africa and the Irish Free State.

(3) A self-governing dominion with membership of the Imperial Conference, but without membership in the League of Nations: Newfoundland.

(4) Two self-governing colonies, with a wide but not unrestricted autonomy, and not entitled to representation at the Imperial Conference: Malta and Southern Rhodesia.

(5) Crown colonies, or colonies not possessing responsible Government, that is, colonies in which the executive Government is controlled by the British Government through the secretary of state for the colonies. The legislatures in these cases may be entirely independent of the executive, as in Bahamas, Bermuda and Barbados, with their nominee upper houses and their elective as-

FIG. 3.—MAP OF THE BRITISH EMPIRE IN 1837. SINCE 1714, INDIA AND THE GREATER PART OF CANADA AND AUSTRALIA HAD BEEN ADDED WHILE SUB-ARCTIC CANADA, INCLUDING VICTORIA ISLAND AND BAFFIN LAND, ALTHOUGH NOT COLONIZED, WAS CLAIMED BY THE CROWN. CAPE COLONY WAS ALSO ANNEXED DURING THIS PERIOD, AS WERE THE STRAITS SETTLEMENTS

semblies, but normally are, either in case of emergency as in Ceylon or regularly, subject to control either because there is an official majority or because the governor alone constitutes the legislature. To the Australian Commonwealth are attached, as dependencies administered on Crown colony lines, Papua and Norfolk Island; to New Zealand, the Cook Islands and the Ross dependency.

(6) Protectorates administered on colonial lines. These differ from colonies mainly in that they are not annexed to the British Crown, and their inhabitants are not British subjects. The protectorate status in such cases normally precludes annexation when administration has become more developed; it usually rests on promises of protection granted to more or less uncivilized tribes and the Administration often makes wide use of the agency of chiefs in government, especially in Nigeria and Uganda.

(7) Protected States, retaining distinct personality. Some of them, as Sarawak, possess internal autonomy, while in the case of others, like Zanzibar, the administration is carried on in effect by British officers.

(8) India, including British India and the Indian States. The former is administered under the governor-general, and his executive council, appointed by the Crown; the latter possess various degrees of internal autonomy. India as a whole possesses membership in the League of Nations and representation at the Imperial Conference. (See INDIA.)

The Mandated Territories, held under mandate by Great Britain, Australia, New Zealand and South Africa though under British administration, are not parts of the British empire and will be considered separately below.

These classes fall into four main groups: (A) the self-governing communities (Nos. 1, 2, and 3 above, comprising the United Kingdom of Great Britain and Northern Ireland, and the dominions); (B) Malta and Southern Rhodesia (No. 4); (C) India; (D) the non-self-governing communities (Nos. 5, 6, and 7). The term "British Commonwealth of Nations," often used since the World War as an alternative to "British Empire" and first officially so used in the Irish Treaty of 1921 (see below), implies self-government and is a more suitable description of Group A, and, with reservations, of Groups B and C, than of group D.

#### A. GREAT BRITAIN AND THE DOMINIONS

The political development of the United Kingdom is dealt with in other articles (*see ENGLISH HISTORY*, etc.). The political development of the dominions has proceeded on the same lines. In fact it is best described as a process of assimilation by which British citizens in the overseas territories now occupied by the dominions have acquired in course of time, stage by stage, the same political status as British citizens in the mother-country. The keynote of this process has been equality. It was inequality which at root brought about the secession of the old American colonies. Only on a basis of equality can the existing union between the mother-country and the dominions be maintained.

**The American Colonies.**—The first colonists on the North American coast could not, of course, exercise equal political powers with those enjoyed by the kinsmen they had left at home. Their isolation, the vast distance which, as measured in time of transit, then separated America from England, made it impossible for little groups of pioneer colonists to be represented in the English parliament or to take any part in the wider political affairs of the empire as a whole. But in the conduct of their own local affairs they possessed from the first a certain measure of equality. They were Englishmen, and they retained in their new homes the old-established rights and usages of Englishmen and among others the right to representative Government. In each colony, soon after its foundation, a representative assembly was established, on the model of the House of Commons, which enacted legislation for the colony, including taxation to meet the cost of its administration. But the executive was independent of the legislature; for, whereas in England the principle of responsible Government, *i.e.*, that the executive should be responsible to the legislature, began to be established in the course of the 18th century, the colonial executive, the governor and other officials, was responsible in most colonies only to the Crown or the minister who advised the Crown. Otherwise the American colonies were virtually independent in their local concerns, in which the British Government in those days took little interest. Externally, however, they were quite subordinate. Their trade was controlled by a system of navigation acts and other legislation, enacted by the British parliament as part of a

"commercial system" applied to the whole empire. Nor, of course, could the colonists take any part in the foreign affairs of the empire. While the colonies were relatively young and small, this system worked well enough; and even in the middle of the 18th century, when their population had increased to about two millions, it still endured. Despite occasional friction between executive and legislature, the colonists felt themselves sufficiently free and self-governing internally; and the external restrictions of the trade laws did not seem burdensome because on the whole it was economically profitable, and, if need be, it could be, and was, evaded by smuggling. But the system was bound to seem less tolerable as soon as anything occurred to emphasize the inequality of status it involved; and when the British Government attempted to raise money for the cost of maintaining troops in America, partly by direct taxation and partly by stiffening up the administration of the trade laws, the colonists, although the troops were required mainly for their own defence, revolted and the system collapsed.

**The Crisis in Canada.**—Fifty years after the American Revolution, British statesmen were confronted with a similar crisis in those colonies in North America which had survived the schism or had been established since. Except for the decision never again to tax the colonies for revenue, the new political system was much the same as the old. The colonies possessed local representative government and nothing more; and in 1837 a period of increasing tension in Upper and Lower Canada, mainly due to the fact that the legislatures had no control over the executives and intensified in Lower Canada by race-antagonism between French and British, culminated in rebellions. They were small, ill-organized, and easily suppressed; but they were a symptom of grave political disease, and when Lord Durham (*q.v.*) was sent out to investigate it, he declared in his famous *Report* that the only cure was to give the colonists the same kind of self-government in all their internal affairs as that enjoyed by Englishmen at home—in other words, responsible as well as representative Government. After some hesitation Durham's advice was adopted. Responsible Government was established in the North American colonies between 1846 and 1849 and in Australia and New Zealand a few years later. It was delayed in South Africa owing to the native problem.

This was the most crucial step in the process of political assimilation. For, once it had been conceded that the people of a colony had the same right as the people of the mother-country entirely to control their local affairs, both executive and legislative, it was difficult to refuse their claim for a wider measure of equality. Thus Durham's idea that, if internally quite self-governing, the Canadians would willingly leave the control of external affairs, of which the most important were trade and foreign policy, to the British Government and parliament, soon proved fallacious. In 1859 after a brief controversy, the demand of the province of Canada to be free to set up protective tariffs not only against foreign goods but also against British was conceded. And from that day to this it may be said that the advance of the colonies or dominions towards complete equality has never been resisted.

**Unification of the Dominions.**—The most important stage in this advance was the change from colonies into dominions, *i.e.*, the unification of contiguous groups of colonies into national entities. By this means colonies, which in their separate existence had been small and weak, like unco-ordinated English counties, attained a size and strength which made them at least potentially comparable with the mother-country. Unification also made possible the steady growth of a distinctive national spirit. As at most other stages, the precedent was set by the oldest group of colonies. In 1867 the four chief North American provinces, on their own initiative but with full consent in Britain, constituted themselves a federation under the title of the "Dominion of Canada"; hence the modern use of the word "Dominion." The other provinces, existing or created later, all joined the federation in due course. Newfoundland has chosen to remain separate. For various local reasons the other groups of colonies were slow to follow Canada's lead. The Commonwealth of Australia was not created till 1900 and the Union of South Africa not till 1909. The Dominion of New Zealand, which had never been divided into separate colonies, obtained a unitary constitution in 1870.

**Military Defence.**—Meantime the colonies were beginning to assume the duties as well as the rights of self-government. Though they still made no claim for a share in the control of foreign policy, they were prepared in the second half of the 19th century to relieve the mother-country of part at least of the burden of their military and naval defence. In evidence given before a departmental committee in London in 1859 it was shown that at that time the colonies were free from almost every obligation of contributing either by personal service or money payment towards their own defence, and that the cost of military expenditure in the colonies in the preceding year had amounted in round figures to £4,000,000. A committee of the House of Commons sat in 1861 to consider the question, and in 1862 it was resolved, without a division, that "colonies exercising the right of self-government ought to undertake the main responsibility of providing for their own internal order and security, and ought to assist in their own external defence." The decision was accepted as the basis of imperial policy. The first effect was the gradual withdrawing of imperial troops from the self-governing colonies, together with the encouragement of the development of local military systems by the loan, when desired, of British military experts. In 1868 the Canadian Militia Act gave the organized nucleus of a local army to Canada. In the same year the British troops were withdrawn from New Zealand, leaving the colonial militia to deal with the native war still in progress. In 1870 the last British troops were withdrawn from Australia, and in 1871 from Canada (except from the naval stations); and in 1873 it was officially announced that British military expenditure in the colonies was almost "wholly for imperial purposes." In 1875 an imperial officer went to Australia to report for the Australian Government upon Australian defence. The appointment in 1879 of a royal commission to consider the question of imperial defence, which presented its report in 1882, led to a considerable development and reorganization of the system of imperial fortifications. Coaling stations were also selected with reference to the trade routes. The colonial military forces were relatively weak and mainly composed of militia and volunteers until in 1909 defence Acts (amended in 1910 after consultation with Lord Kitchener) established compulsory military training in Australia and New Zealand. South Africa followed suit in 1912.

**Naval Defence.**—It was always evident that, whatever land forces might be maintained in the colonies, their security would mainly depend on sea-power; and in 1865 a colonial naval defence act was passed empowering the colonies to provide ships of war and seamen for their own defence and in case of need to place them at the disposal of the British Government for imperial purposes. After the Colonial Conference of 1887 (*see below*) it was agreed that the Australasian squadron of the British navy should be increased and that Australia and New Zealand should contribute £126,000 a year towards the cost. After 1897 Cape Colony, Natal and Newfoundland contributed smaller sums. But in 1902, while the Australasian and South African contributions were increased, Canada declared that she preferred to create a local navy of her own rather than contribute to the British treasury. Thenceforward the two methods were combined. As a result of the alarm created in 1909 by the growth of the German navy, Australia began to build an Australian navy of first-class vessels; New Zealand presented a battleship to the British navy but adopted the "local navy" policy in 1913. Canada began a local navy policy by buying two small cruisers, and in 1912, under Sir R. L. Borden, proposed to build three battleships or battle-cruisers to form part of the British navy so long as the situation in Europe was dangerous, but this proposal was rejected by the senate. South Africa continued its contribution for the time. In general it may be said that by 1914 the idea of contributions had fallen into disfavour as incompatible with the growing sense of dominion "nationhood," but it was always recognized that the local navies which they preferred to build would coalesce with the British navy in time of war.

These developments in military and naval defence had not taken place without close consultation between the British and colonial authorities. The personnel of the Colonial Defence Committee

FIG. 4.—THE BRITISH EMPIRE TO-DAY, COVERING MORE THAN 13 MILLION SQUARE MILES OF THE EARTH'S SURFACE. ITS POPULATION, INCLUDING THE MANDATED TERRITORIES, IS 450 MILLION. IT HAS 7 MEMBERS IN THE LEAGUE OF NATIONS—GREAT BRITAIN, IRISH FREE STATE, COMMONWEALTH OF AUSTRALIA, INDIA, THE DOMINIONS OF CANADA AND NEW ZEALAND, AND THE UNION OF SOUTH AFRICA

created in 1886 was purely British; but it was mainly to discuss imperial defence that the first Colonial Conference was held in 1887. In 1901-02 the Committee of Imperial Defence was set up, under the British prime minister but with dominion representatives, and it became the supreme consultative authority on the question. Colonial troops, meanwhile, had begun to take part in imperial wars. Contingents from Canada and New South Wales served on the Sudan expedition of 1885; and 30,000 men from Canada and Australasia served in the Boer War of 1899-1902.

**The Dominions and Foreign Policy.**—It was not, however, till the eve of the World War that the dominions began to concern themselves with the foreign policy of which armies and navies were but the ultimate instruments. Far from the storm centre in Europe and immersed in the tasks of internal development, they were content to leave the issues of war and peace in the hands of the British Foreign Office. Thus, when, in the jubilee year of 1887, a conference of the representatives of the British and colonial Governments was held in London, foreign policy was not discussed, nor at succeeding colonial conferences which were mainly concerned with defence, tariffs, communications and other minor subjects. The conference of 1907 marked an advance in the status of the dominions towards equality with the United Kingdom; for it decided that the conference, which was to be called "Imperial" in future instead of "Colonial," should consist of the prime ministers of the component units, on a footing of equality, the British prime minister taking the chair instead of the colonial secretary as heretofore. It was also decided that the conference should meet every four years; and at the conference of 1911 the dominion prime ministers were for the first time admitted into the secrets of foreign policy. At the same time the question of enabling the dominions to take their part in the control of foreign policy was raised by Sir J. Ward on behalf of New Zealand. He proposed the establishment of an imperial Government and parliament to deal with such matters of common concern as foreign policy—in fact a kind of imperial federation—but the proposal was rejected by the representatives of the other dominions and on behalf of the United Kingdom by H. H. Asquith, who declared that the responsibility

for foreign policy could not be shared. There the matter rested till the outbreak of the World War; for, though there was considerable private discussion in all parts of the empire about the means of co-operation in foreign affairs and the possibilities of federation, in which discussion the unofficial "Round Table" organization took a prominent part, the dominion Governments were more concerned with confirming and advancing their separate national status than with devising methods of united action. Thus, in 1912, a significant step was taken to assert the distinct personality of the dominions. Hitherto at international conferences the King had been represented by one delegation only, which might contain dominion representatives, but which acted as a whole; at the radio-telegraphic conference of that year the King was represented by distinct delegations acting under separate full powers, those granted to the dominion representatives empowering them to act for the dominions. This recognition for external purposes of a distinction long familiar in matters of internal sovereignty was followed in the Conference on the Safety of Life at Sea in 1913-14.

**The Empire in War.**—The World War came so swiftly, on Aug. 4, 1914, that it was impossible to consult the dominions, but all the dominion Governments promised aid, placing under the Admiralty their naval forces, comprising the Australian fleet and the small forces of Canada and New Zealand. Similarly, the troops raised by the dominions for overseas service were voluntarily placed under British command, though in the last year of the war the Canadian Expeditionary Force had some independence.

In the earlier period of the war the Governments were too busy to hold the Imperial Conference due under its constitution to meet in 1915; but, on the resignation of Asquith in 1916 and the advent to office of D. Lloyd George, the determination to secure greater efficiency in the conduct of the war and the more complete mobilizing of the strength of the empire led to the summoning of representatives of the dominions and of India—not a member of the conference under the constitution of 1907—for discussions with the British Government. Meetings in 1917 and 1918 took a double form; on the one hand the immediate issues affecting the war and the conditions on which peace might be made were

debated at sessions of the Imperial War Cabinet, while matters of secondary importance were dealt with by the Imperial War Conference.

The Imperial War Cabinet, closely connected with the British cabinet, was a cabinet of quite new character, a "cabinet of governments" as Sir R. L. Borden described it. There was no prime minister on whom it depended; each dominion, India and United Kingdom were represented by independent delegates, the British prime minister presiding merely as *primus inter pares*. There was no joint responsibility, and the cabinet could only pass resolutions, not take decisions. It remained for the several cabinets to decide what effect to give to the resolutions, to which the dominion representatives agreed only on the understanding that they must be approved by their colleagues and parliaments. On the other hand the meetings afforded a valuable opportunity for the dominion and Indian representatives to express their views, and thus, in some measure, to share in the supreme direction of the forces of the empire, though final responsibility necessarily rested with the British Government in view of the preponderant share of the burden of the war borne by British resources. It was recognized that the new departure was essentially due to war conditions, but it was agreed, in 1917, that the constitutional relations of the empire should be reconsidered at a conference to be summoned after peace was achieved. In the discussion on this question the federal idea was again repudiated; and it was resolved, on Sir R. L. Borden's motion, that any new system must maintain "all existing powers of self-government" enjoyed by the dominions and recognize them "as autonomous nations of an Imperial Commonwealth."

**The Peace Conference.**—The second meeting of the Imperial War Cabinet held in 1918 was followed shortly by the final defeat of the German forces, and the body was reconvened to consider the terms of peace, being transformed finally into the British Empire delegation to the Peace Conference of 1919. The unity which had hitherto marked the representation of the empire was now difficult to maintain; it had been contemplated by the British Government that the empire should speak at the Peace Conference through a single delegation. It was, however, felt by the dominions that they must have the same measure of recognition as the minor powers taking part in the conference. A compromise was, accordingly, reached. Under this, in addition to the British empire delegation on which the dominions might be represented from time to time on the panel system, there were recognized delegations from Canada, Australia, South Africa, New Zealand and India, Newfoundland being omitted in view of her small population. The delegations were accorded the right of being heard on matters specially affecting them on the same footing as the minor belligerent Powers, but importance really attached to the influence which the dominion representatives had in deciding, in the discussions within the British empire delegation, what attitude should be adopted by that body, or, when matters were left to the heads of the delegations of the five Great Powers, by Lloyd George.

The form in which the Treaty of Versailles was concluded marked a further confirmation of "Dominion Status" (as it was now called) on Sir R. L. Borden's principle of "equal nationhood." Thus the dominion delegates received their full powers to negotiate and sign separately from the Crown on the separate advice of their respective Governments; and, while the British delegates signed the treaty for the British empire generally, the dominion delegates signed each for his own dominion. Similarly, the dominions insisted that the ratification of the treaty should not be carried out until approval of it had been expressed by their parliaments, and, after demur on the ground of delay, this demand was conceded by the British Government. The same procedure was adopted in the international negotiations on sea-power in the Pacific at Washington in 1921. A similar British delegation attended the conference, and the treaty was signed and ratified separately like the Treaty of Versailles.

**Membership of the League of Nations.**—Still more important was the decision taken at the request of the dominions to secure them an independent position in the League of Nations as created by the Treaty of Versailles. This was done by including in the list of original members the British empire, followed imme-

diately by the dominions and India, ignoring the United Kingdom altogether. The effect was to confer on the dominions and India for all purposes of the League of Nations an international status apart from the British empire, which was to be represented at Assembly meetings by delegates appointed by the British Government. It was ruled, too, that the dominions were eligible for election to the Council of the League to fill the places left open to election, despite the fact that the British empire as such had a permanent place on the Council. At the Seventh Assembly (1927) Canada was elected to the Council.

The dominion representatives, instructed by their several Governments, are free of course to speak and vote at Geneva as they please; and on minor questions British and dominion representatives have sometimes taken different sides. But on major questions general agreement has been maintained by previous consultation. Inevitably, however, the attitude of the distant dominions towards affairs in Europe is not quite the same as that of Britain. Thus the obligations of the Covenant are regarded, in one vital matter, rather differently by Britain and by the dominions and India. As a European Power Britain accepted as necessary the implications of the guaranty of the territory and independence of members contained in Article 10. Canada, however, only acquiesced in it originally under protest, and later pressed, though unsuccessfully, for the formal modification of the article; similarly the Geneva Protocol of 1924 proved unacceptable to the dominions and India, and except in New Zealand considerable reluctance was shown to accept obligations under the Locarno Pact of Oct. 16, 1925, which exempted the dominions and India from obligation unless expressly accepted by their Governments. On the other hand, the dominions and India showed interest in the carrying out of the Labour clauses of the Treaty of Peace under which their distinct individuality was expressly recognized.

The recognition of the dominions as distinct entities conceded in the Treaty of Versailles and admitted in the negotiation and signature of the other treaties with ex-enemy Powers, led to the claim by Canada for the right of separate diplomatic representation where that was desirable in her own interests, and primarily in the United States. The claim was conceded, subject to the willingness of the United States Government, to permit such representation, and to the declaration that it was not the intention of either the British or the Canadian Government to diminish in any degree the diplomatic unity of the empire. The assent of the United States was at first doubtful, as one of the objections there urged against the constitution of the League of Nations was that it accorded separate votes to different parts of the empire, but ultimately the necessary approval was accorded. The Canadian Government did not take advantage of the concession till 1926, when a Canadian minister at Washington was appointed. Meantime, since the privilege was automatically extended to all the dominions, the Government of the Irish Free State had appointed an Irish minister at Washington in 1924. It is understood that such ministers will only deal with matters affecting the interests of their dominions and will act in close harmony with the British ambassador. In 1928 the Canadian Government announced its intention of making further appointments at Paris and Tokyo.

**The Conference of 1921.**—The sense of "nationhood" which had been greatly stimulated by the World War, was satisfied in most of the dominions by these acknowledgments of their separate status; and in foreign affairs they were content with the existing system of regular conferences and constant communication during the intervening periods. Thus nothing came of the resolution of 1917 in favour of holding a constitutional conference after the war. A conference met in 1921, only to declare itself satisfied that no reconstruction of imperial relations was desirable. The great majority of the people in the dominions were satisfied that an organization which had weathered the war would be adequate for the future. The value of the plan of conferences, on the other hand, was strikingly confirmed at this meeting, for it was found possible to adjust the discordant views of the dominions and Great Britain regarding the renewal of the Japanese alliance by adopting the policy which culminated in the Washington Conference and the treaties of 1922.

FIG. 5.—MAP SHOWING TERRITORIES (IN BLACK) CEDED BY GREAT BRITAIN FROM 1714 TO PRESENT DAY. THE 13 STATES FORMING THE AMERICAN COLONIES DECLARED THEIR INDEPENDENCE ON JULY 4, 1776, AND THIS WAS ACKNOWLEDGED BY GREAT BRITAIN ON NOV. 30, 1782. JAVA, GUIANA, REUNION, PONDICHERRY, HELIGOLAND, ST. PIERRE AND MIQUELON HAVE BEEN GIVEN UP OR EXCHANGED AS A RESULT OF VARIOUS TREATIES BOTH POLITICAL AND ECONOMIC

Later in 1922, however, a distinct discrepancy of feeling between the nations of the commonwealth was manifested when Lloyd George asked the dominions to support his Chanak policy. Australia and New Zealand, interested in anything which might affect the security of the Mediterranean sea-route, acquiesced; but Canada and South Africa took the view that, as they had not been effectively consulted on the policy which led to the situation, they could not be expected blindly to pledge themselves to military support. The settlement of the immediate issues removed the difficulty for the moment; but further questions were raised in March 1923, in connection with the signature of a treaty between Canada and the United States regarding the halibut fisheries. Hitherto, in accordance with the rule laid down by Lord Ripon in 1895 and Sir E. Grey in 1907, any political treaty involving a dominion had been signed not only by a dominion but also by a British representative. Canada now contended that, as the treaty affected Canada only, it should be signed by her representative alone; and after some discussion this contention was accepted.

**The Irish Treaty.**—Meanwhile, the aspect of the British empire as an informal alliance of autonomous states had been emphasized by the conclusion of the treaty of 1921 between the United Kingdom and the Irish Free State. The status of a dominion was by that measure formally granted and the instrument was styled a treaty, although concluded by the British Government merely with representatives of forces in armed rebellion against the Crown. The British Government held that, despite the name, the treaty was not one in the sense of international law, since it did not confer independence but merely dominion status. It therefore maintained the view, contrary to that of the Irish Free State, that the provisions of the Covenant of the League of Nations for the registration of treaties did not apply. The new State was admitted in 1923, with the assent of the empire, to membership of the League of Nations. The adoption of a special flag and the enactment of a distinct Irish citizenship marked the assertion of autonomy. Canada in 1921 had similarly defined Canadian nationals; the definition, however, was necessary to distinguish between British subjects in general and Canadian British subjects in particular

in considering their eligibility for nomination by Canada to stand as candidates for election to the Permanent Court of International Justice. In South Africa in 1927, after bitter party controversy, a compromise was reached, providing for a special South African flag but also recognizing the Union Jack as denoting South Africa's membership in the empire.

**Conference of 1923.**—In 1923 the Imperial Conference met again, the Irish Free State being represented for the first time. The chief question affecting inter-imperial relations discussed at this meeting was the treaty question. It was agreed that treaties should normally be negotiated and signed, under full powers granted by the King, by representatives of the part or parts of the empire affected, and that in negotiating any treaty it should be the duty of the Government primarily concerned to secure that any other Government which was affected should be invited to take part in the negotiations; in the case of international conferences the procedure adopted at the Paris Conference should be followed. Ratification of treaties thus negotiated should be expressed under the same conditions—that is, on the request of the Government or Governments concerned. It was understood that in all such international business Great Britain and the dominions would have due regard to each others' interests and those of the empire as a whole.

The conference also discussed foreign policy. It approved the principle of supporting the League of Nations, and reaffirmed the doctrine laid down in 1921, that each part of the empire should make provision for local defence; it also approved the view that the naval forces of the empire should be equal to those of any other power, and that suitable bases should be provided, with special reference to the British Government's proposals about Singapore. The absolute autonomy of the dominions was, however, stressed, and no pledges of aid in the maintenance of the navy were offered, the decision resting with the dominion parliaments.

An unfortunate misunderstanding, however, arose out of the conference. Apparently it was held that the discussions there of the terms of peace to be made with Turkey involved the dominion Governments in responsibility for the Treaty of Lausanne when finally agreed upon by the British representatives, who alone took

part in the discussions. When, however, Canada was asked to approve of the ratification of the treaty she made it clear that while she took no exception to ratification, the responsibility for it, and for the obligations which might be imposed on the empire under its terms, must rest with the British Government only. The doctrine was thus established that the dominions would only accept active obligations when they had taken part in the negotiations and agreed to their results. A further representation from Canada resulted in the admission of this principle by the British Government in connection with the London Reparations Conference of 1924, though lack of time prevented the adoption there of any other than a makeshift arrangement for the special representation of the dominions. The British Government then proposed that the question of more effective consultation on international subjects should form the subject of a special conference, but its fall from office was followed by an intimation that further experience of the working of existing arrangements was desirable, a view acquiesced in by the dominions.

In 1925 the prime minister of the Australian Commonwealth arranged to station in London a liaison officer to keep him fully informed on foreign political questions and the views of the British Government; but neither this device nor the alternative suggestion of sending a member of the dominion cabinet to act as minister resident in London received general approval in the dominions, largely because such a minister would inevitably cease to be in effective touch with dominion feeling and would be apt to commit his Government to British views, while, if he merely acted as a channel of information, his employment would hardly serve any useful purpose. Consultation, therefore, was conducted, as before, mainly by telegram in dealing with the Geneva Protocol of 1924 and the Locarno Pact of 1925; and, since no *ad hoc* conference could be held nor empire delegation formed, a clause was inserted in the Locarno Treaty exempting the dominions from its obligation unless expressly accepted by them.

The attitude revealed by these consultations was one of reluctance on the part of the dominions to take an active part in British foreign policy save in so far as it directly concerned their interests. It was admitted that the dominions might be involved in war by British action, which they could not as matters stood effectively control, but it was recognized that it remained for each parliament to decide whether in the event of hostilities it would afford aid, and, if so, in what manner, to Great Britain. The constitutional position was summed up in Article 49 of the Irish Free State Constitution, which provided that, except in the case of invasion, the State could not be involved actively in war save with the assent of its own parliament, a doctrine which was also definitely approved by Canada and accepted by the other dominions.

**Conference of 1926.**—The process of assimilation had thus been as far as possible completed. In foreign affairs as in all else the dominions were now equal "in status, though not in stature," with the older and larger Britain. As an illustration of this fact, the Colonial Office in Downing street was divided in 1925 into two departments so as to distinguish between the dominions and the non-self-governing Crown colonies, and a new office of secretary of State for dominion affairs was created. For the time being this new office was held by the colonial secretary, Mr. Amery, conjointly with his old one. In some quarters, however, and specially among the Nationalist Party in South Africa which now, headed by General Hertzog, came into power in alliance with the Labour Party, it was still supposed that the dominions were in some degree subordinate to Britain. At the conference of 1926, therefore, it was decided to attempt a written definition of inter-imperial relations, and a committee, with Lord Balfour as chairman, drew up a report which thus defined the "position and mutual relation" of Great Britain and the dominions: "*They are autonomous Communities within the British Empire, equal in status, in no way subordinate one to another in any aspect of their domestic or external affairs, though united by a common allegiance to the Crown and freely associated as members of the British Commonwealth of Nations. . . . Every self-governing member of the Empire is now the master of its destiny. In fact, if not always in form, it is subject to no compulsion whatever.*" This report was accepted

by the conference and by public opinion in all parts of the empire. General Hertzog declared himself quite content that South Africa should remain within the empire on these terms.

The committee also dealt with some of the forms which no longer corresponded with the facts. To fit the new position of the Irish Free State it recommended that the phrase "United Kingdom of Great Britain and Ireland" should be dropped from the King's title which should read, "George V., by the Grace of God, of Great Britain, Ireland and the British Dominions beyond the Seas King, Defender of the Faith, Emperor of India." It declared that the governor-general of a dominion occupies the same position in the dominion as the King in Great Britain, that he is not the representative or agent of the British Government, and that he should not act as the channel of communication between his Government and the British, but that communications should be in future between Government and Government direct. It further stated that the old customs of "disallowance" or "reservation" of dominion legislation by the King on the advice of his British ministers—customs which had fallen into disuse—were no longer constitutional since the King, being advised on dominion matters by dominion Governments, could not properly be advised against these governments' views by the British Government. With reference to the survival of those and similar forms in imperial acts of parliament, it was decided to appoint another committee to consider the best means of attaining legislative equality. On the question of the right of appeal from dominion courts to the judicial committee of the Privy Council—a right which was considered in some quarters, specially in the Irish Free State and Canada, as incompatible with equal status—the committee reported that the British Government desired the matter to be settled in accordance with the wishes of the dominions but that, as all parts of the empire were concerned, no change ought to be made without consultation and discussion. Turning to foreign affairs, the committee confirmed and supplemented in detail the agreement of the conference of 1923 on treaties; declared that the major share of the responsibility for foreign policy as for defence must continue for some time to rest with the British Government, but that no dominion could be committed to active obligations without its own Government's consent; and pointed out "the desirability of developing a system of personal contact, both in London and in the dominion capitals, to supplement the present system of inter-communication." (In 1927 an official was appointed as agent and intermediary for the British Government in New Zealand; and in 1928 in Canada and South Africa.) The report as a whole might have seemed to be more concerned with denying inequality than with affirming unity, if it had not contained a passage with which this section may be fitly closed. "The British empire is not founded on negations. It depends essentially, if not formally, on positive ideals. Free institutions are its life-blood. Free co-operation is its instrument. Peace, security and progress are among its objects. . . . And, though every dominion is now, and must always remain, the sole judge of the nature and extent of its co-operation, no common cause will, in our opinion, be thereby imperilled."

#### B. MALTA AND SOUTHERN RHODESIA

These two small units of the empire stand in a class by themselves, with a status between that of a dominion and that of a Crown colony. Under the old Crown colony *régime* the desire of the Maltese for self-government led to persistent agitation and even to the suggestion that Malta should be annexed to Italy; but in 1921 the position was stabilized by the grant of a measure of self-government akin to that introduced in India by the Act of 1919 (*see below*). Full responsible Government with an elected assembly was conceded for the control of all domestic affairs; but the control of external affairs and defence was "reserved" for the governor and a nominated council. Southern Rhodesia till 1923 was administered on Crown colony lines by the British South Africa Company; but in that year, after the financial claims of the company had been met by agreement with the British Government, the colony was annexed to the Crown and responsible Government instituted. It is not so complete, however, as, e.g., in Newfoundland, since the powers of the legislature are limited

touching the interests of the natives and other matters touching purely local questions, and the right of disallowance by the Crown is maintained.

### C. INDIA

The Indian constitution is fully described elsewhere (*see* INDIA). But a brief statement must be made here to explain the status of India as part of the empire. The services rendered by the people of India in the war and the emphasis laid by the Allied and Associated Powers on the principle of self-government made it difficult for the British Government and parliament to reject the demand of Indian politicians for further autonomy. Accordingly the Government of India Act of 1919, with the declared intention of leading up by gradual stages to responsible Government, introduced a constitutional system known as Dyarchy, by which the field of Government in the provinces was divided into "reserved" and "transferred" subjects, the former to be controlled by the governor and a nominated executive council, the latter by the governor acting with Indian ministers responsible to elected legislative councils. At the same time a mainly elective legislature was created for all British India; but the all-India executive (the governor-general and council), while acting as far as possible in harmony with this legislature, was not to be responsible to it but only to the British Government and parliament. This constitution worked, not without friction, but not unsuccessfully, till in 1927, in accordance with the intentions of 1919, a commission of M.P.s was set up, with Sir John Simon as chairman, to report on what further political progress, if any, could be made. More important for the purpose of this article is the external status now accorded to India. Representatives of India were invited, together with the dominion prime ministers, to attend the Imperial War Cabinet and Conference in 1917 and 1918; and like the dominions India became an original member of the League of Nations. Internationally, therefore, India enjoys, in form, the status of a dominion; but, since India is not wholly self-governing and since, in particular, her foreign policy and defence are controlled by an executive not responsible to an Indian legislature, this position is anomalous and represents the potentialities of the future rather than the realities of the present. At the same time the new status enables the Government of India to seek redress for the grievances of Indians domiciled in the dominions by representation at the Imperial Conference or directly to dominion Governments instead of through the mediation of the British Government. At the conferences of 1921 and 1923 the representatives of India were satisfied with the assurances of all the dominions except South Africa. The dispute with South Africa, where the difficulties arising from the differential treatment of Indian immigrants had been far more serious than elsewhere, was settled by agreement in 1926 as the result of commissions from South Africa to India and vice versa. In 1927, a distinguished Indian, Sir S. Shastri, was appointed by the Government of India to act as its agent in South Africa and assist in carrying out the agreement.

### D. THE NON-SELF-GOVERNING COLONIES

This vast congeries of many diverse units with varying constitutions can be grouped in one political class because none of them enjoys full responsible Government and in all of them (except the Bahamas, Barbados and Bermuda, in which independent legislatures have survived from earlier times) the executive, which is responsible only to the secretary of State for the colonies, can control the legislature. In some cases the governor alone has power to legislate sometimes because, as at Gibraltar, the colony is little else than a fortress or naval station, but more often because the population of the colony or protectorate consists almost entirely of politically backward native peoples. In other cases a legislative council or assembly exists, sometimes wholly nominated, sometimes partly elected, but always with a majority of official or nominated members through whom the executive can keep control. Furthermore, the colonial secretary retains the power to control legislation, and especially taxation and expenditure, either by instructions to the governor or by subsequent disallowance.

In this field of the empire, as elsewhere, the war led to political advance. In the West Indies an elective element was introduced into the legislative councils of Trinidad and the Leeward Islands, and an elective majority was established in the Jamaica council, subject to the governor's power to pass essential legislation by counting only official votes. A commission was appointed in 1927 to consider changes in the constitution of Ceylon. In the West African colonies, the natives of which had served in large numbers and with heavy losses in the African campaigns, mainly as porters, native representatives were included in some of the legislative councils, partly on an elective basis. In East Africa, more especially in Kenya, the problem is complicated by the fact that the climate of the highlands enables white men to make their homes there, with the result that there is a substantial minority of white settlers. In Kenya the Europeans (mainly British), who numbered 12,529 in 1926, are demanding responsible Government. It is also urged that Kenya should be joined with Uganda, Tanganyika, and Zanzibar in a federal union. In 1927 a commission was appointed, with Sir Hilton Young as chairman, to examine and report on those and allied questions.

**The Mandated Territories.**—A further innovation in constitutional usage was introduced by the creation of the mandatory system (*see* MANDATE), and the allocation by the principal Allied Powers to the British Government of mandates for Mesopotamia, renamed Iraq, Palestine, portions of Togoland and the Cameroons, and German East Africa, renamed Tanganyika Territory; to Australia for German New Guinea; to New Zealand for Western Samoa; to the Union of South Africa for German South-West Africa; and to the British empire for the Island of Nauru. The terms of the mandates approved by the League of Nations authorized the administration of Togoland, the Cameroons, New Guinea, Western Samoa, Nauru and South-West Africa as portions of the territory of the mandatory power, subject to the observation of certain principles in the interest of the natives and under obligation to report annually to the League, whose permanent commission on mandates was established to deal with such reports; authority was expressly given for the application to such territories of the customs and immigration laws of the mandatory State.

In the case of Tanganyika, Togoland and the Cameroons, further restrictions were imposed, providing for equal treatment of nationals of members of the League. Togoland and the Cameroons were attached for administration to the Gold Coast and Nigeria. Tanganyika was given a constitution of the usual protectorate type. Iraq, which was at first to have been administered directly by Great Britain, was recognized by treaties of 1922-24 as an independent kingdom, and the obligation undertaken as a mandatory power by Great Britain was held by the council of the League to be satisfied by the acceptance of responsibility for the due carrying out of the treaties, which, however, were to lapse if Iraq should be admitted a member of the League before their expiry by lapse of time in four years. This period, however, was extended to 25 years by the treaty of Jan. 13, 1926, in accordance with the recommendation of the League Council of Dec. 16, 1925, for the settlement of the boundary with Turkey. By a further treaty of Dec. 1927 Great Britain formally recognized Iraq an independent State, and agreed to support Iraq for admission to the League of Nations in 1932. It was also decided to negotiate a revision of the existing military and financial agreements. In the case of Palestine the mandate was granted subject to the obligation, voluntarily assumed by Great Britain, of furthering the establishment of a home for the Jews; efforts to carry this out resulted in strong resistance by the Arab majority, which declined to work the constitution conferred in 1922, with the result that all executive and legislative power remains in the hands of the representatives of the mandatory power.

### GENERAL

**A League of Nations.**—To the student of world-affairs there is no political community more interesting than the British empire; for it embraces part of every continent and includes sections of all the major races of mankind, with their diversities of colour,

creed and culture. It is, so to speak, a microcosm of the world; and consequently all the main problems of world society can be found in operation within it. Thus there is no richer field for the study of the problem of nationality. The British empire can be regarded from one aspect as a vast experiment in international relations. The peoples of the British Isles, to begin with, were long ago confronted with the task of adjusting the relations between the four nationalities which had been implanted therein as the outcome of early race-migrations. As regards the English, Welsh and Scots, the task was accomplished by the fusion of Wales with England under the Tudors and by the union of England and Scotland in 1707. Time has confirmed the success of this achievement; for while the smaller nations, the Welsh and the Scots, are harmoniously united in one State with the English, they retain a lively consciousness of their own distinctive nationalities. The problem as between the British and the Irish took far longer to solve; and the solution attained in 1921 after centuries of tragic conflict was not complete, since the Irish of the north-east, though quite distinct in nationality from the British, remain apart from the rest of Ireland and still closely associated with Britain. The same kind of international problem has been solved or is in process of solution in two of the dominions. The relations between British and French in Canada were finally adjusted in 1867 by federation which leaves the French-Canadians free to control their own national life in their old home in the Province of Quebec, while they take their part in the wider Canadian nation through the Federal Government and parliament. Some disputes may occur from time to time about language or religion owing to the overflow of French-Canadians into mainly British-Canadian provinces; but it is generally recognized that Canada's destiny is bi-national and that the dominion is the richer for being able to draw upon two of the greatest languages and cultures of the world. The friction between British and Dutch in South Africa has lasted longer and has been embittered by war; nor was it possible, owing to the local intermixture of the two peoples, to apply the federal solution. None the less, though feeling still runs high at times, as in the flag controversy in 1927, it seems probable that British and Dutch, aided by intermarriage and a sense of common interests, will ultimately settle their differences in a common sentiment for a united South Africa. And, lastly, the dominions and Britain together constitute a unique international society. Each is free and independent, but all are willingly associated under one Crown. It is a league of nations more closely bound together than the League of Geneva by common traditions and sentiments and a preponderance of common blood. The population of the dominions, with their wide unoccupied spaces, will quickly grow more equal to that of Britain and in some cases will eventually surpass it. Whether, with the aid of swifter intercommunication, the union between them will still endure or whether it will break up into wholly separate sovereign states is a question of the greatest importance to the future of the world.

**A League of Races.**—Again the British empire is the most fruitful field for the study of the greater and more difficult problem which lies behind the problem of international relations—viz., the problem of interracial relations.

It was in the empire, in the first place, that the greatest change recorded in all history in the relations between the white and black races was first made. Until the third quarter of the 18th century slavery was accepted by the bulk of European opinion as a natural and necessary institution. European plantations in the tropical or subtropical areas of North and South America and the West Indies were cultivated by gangs of slaves, which were kidnapped, or purchased for spirits or firearms, by European slave-traders, mainly on the west coast of Central Africa, and transported under horribly cruel conditions across the Atlantic. In the course of the 18th century this slave trade became the most lucrative of all trades, and the British, as the leading oceanic traders, obtained the largest share of it. Gradually, however, a humanitarian anti-slavery movement, in which the Quakers took a prominent part, developed in England, and, by persistent appeals to the conscience of the British people, it achieved its object in

four successive stages. (1) In 1772, mainly owing to the efforts of Granville Sharp, the status of slavery was declared illegal in England, and the 14,000 slaves, which had been brought into the country by colonial planters, were set free. (2) In 1807, as the result of a long campaign, headed by Wilberforce, the British slave trade was abolished by Act of parliament; and in 1814-15 the British representatives at the European peace conferences persuaded the other maritime powers to accept the principle of abolition. But the application of the principle in practice was only secured by the unceasing efforts of British diplomacy and by the vigilance of the British cruisers stationed off the west coast of Africa to intercept slave-smugglers. (3) In 1833, after long and bitter disputes with the West Indian planters, parliament abolished slavery itself in all British colonies. Over 800,000 slaves were freed, and £20,000,000 was paid by the British taxpayers as compensation to their owners. (4) Between 1860 and 1880, as the result of negotiations with the sultan of Zanzibar and of naval blockade, the Arab slave trade from East Africa to Arabia and Persia was as far as possible suppressed. Thus it may be claimed for the British people that, if they took the chief part in maintaining the African slave trade and slavery they also took the chief part in their destruction. Nevertheless, slavery was not completely eradicated in Africa until the 20th century. So late as 1927 it was discovered—ironically enough—that although there was no slavery in the British colony of Sierra Leone, a state of domestic slavery was still recognized in the protectorate of Sierra Leone, which had originally been founded as a refuge for liberated African slaves. The discovery of this anomaly aroused great indignation, and on Sept. 22 the legislature of the colony and protectorate of Sierra Leone unanimously endorsed the "Ordinance to abolish the legal status of Slavery," which accordingly came into force on Jan. 1, 1928, and resulted in the technical liberation of some 117,000 persons.

Slavery once abolished, it was possible for new ideas to develop about the relations of the white and the coloured, the advanced and the backward, races; and in course of time these ideas have taken shape, not only in social or economic or religious matters but also in political organization. Here again the empire is a great laboratory of political experiment. At the top of the scale is the Government of India and the attempt described above to enable the diverse Indian peoples to acquire by experience the capacity to govern themselves and so to take their place alongside the dominions in the British commonwealth of nations. The importance of this experiment is manifest; for the position of India within the British empire constitutes a bridge between East and West, and if India can remain contentedly in political association with Britain and the dominions, it will go far to adjust one of the great world-issues of the future—the relations between Europe and Asia. Lower in the scale stands the African question. In the Union of South Africa, in the mandated territory of Tanganyika, and in the wide belt of British colonies and protectorates that stretches across tropical Africa from the Atlantic to the Indian ocean and from the Zambezi to the Nile, a great congeries of native races, mostly negroes or negro stock, presents an unparalleled field of study to the anthropologist, the sociologist, the political scientist and the missionary. As with Asia, so with Africa. The future relations between Africans and Europeans will largely depend on the result of the experiments now in operation in these territories. The character of these experiments varies with local circumstances. In Nigeria, for example, the principle of the "dual mandate," which regards the government as trustee both for the welfare of the natives and for the economic development of their country to meet the needs of the world, can be easily applied because in general the natives themselves own the land and develop its resources. In Kenya, on the other hand, there is more difficulty and dispute, since large areas of the land are owned by Europeans. There are similar differences in politics. In South Africa, the natives of the Cape Province can vote, with an educational and property qualification, alongside with Europeans, for the Union Parliament. In the Transvaal district and in Basutoland, they have developed their own system of local self-government. In Nigeria native representatives are elected

to the legislative council. In Uganda there is an elaborate and old-established quasi-feudal system. In Northern Nigeria there are native States ruled by Muslim emirs. Other examples might be given; but these are enough to show how wide and varied are the race-problems which are being handled within the British empire. The results of them will form no small part of mankind's common stock of political, social and economic experience.

**BIBLIOGRAPHY.**—E. M. Wrong, *Charles Buller and Responsible Government* (1926). R. L. Borden, *Canadian Constitutional Studies*, authoritative on the Peace Conference (Toronto, 1922); A. Milner, *The Nation and the Empire*, speeches illustrating pre-war conception of the empire (1913); A. E. Zimmern, *The Third British Empire*, a brief account of the post-war conception (1926). Among many official publications special attention should be given to *Proceedings of the Imperial Conferences*, especially those of 1911, 1917 and 1926. *The Journal of the Parliaments of the Empire* is a useful record of debates in dominion parliaments. The quarterly *Round Table* provides the best discussion of imperial problems and an authoritative account of current politics in the dominions and India. For the economic development of the empire as a whole the literature is meagre. L. C. A. Knowles, *Economic Development of the British Overseas Empire* (1924) the first volume of a work unfortunately left unfinished, is the only scientific treatment of the subject yet attempted. Information must be sought in works dealing with local fields, such as A. McPhee, *Economic Revolution in British West Africa* (1926). Figures may be found in official publications such as *Statistical Abstract of the British Overseas Dominions*, the *Colonial Reports*, and the *Year Book* of each dominion.

For the government of native races, especially in Africa, the following may be recommended: M. Evans, *Black and White in S.E. Africa* (1911); F. Lugard, *The Dual Mandate in British Tropical Africa* (1922); J. H. Oldham, *Christianity and the Race Problem* (1924); E. W. Smith, *The Golden Stool* (1926). For the abolition of slavery and the slave trade, see R. Coupland, *Wilberforce* (1923), and W. L. Mathieson, *British Slavery and its Abolition* (1926). Biographies of the leading figures in empire history are a valuable source of information. (F. L. L.; R. Co.)

### TRADE AND COMMERCE

The British empire contains nearly a quarter of the world's population, covers one-quarter of the world's area, and is re-

FIG. 6.—PROPORTION OF BRITISH EXPORTS SENT TO FOREIGN AND EMPIRE COUNTRIES FROM 1870 TO 1926

sponsible for over a quarter of the world's food supply. Its economic resources are the greatest which have ever come under the control of any single political system, and for their development the best brains and energy of the empire are required.

Before the World War protagonists of empire trade emphasized the dependence of empire countries upon Great Britain and the duty of the mother country to assist in the development of her children overseas. Since the war, however, attention has been

increasingly directed to another aspect of empire trade, namely, the growing dependence of Great Britain upon empire countries.

The League of Nations, in a memorandum on production and trade, has estimated that world trade in 1925 was 5% above the 1913 volume. Yet in 1925 the volume of British trade was only 76% of the 1913 level, and for the latest available period—the third quarter of 1927—it was only 76.7%. This figure is supported in the import returns of foreign countries where Great Britain is seen to be rapidly losing ground. At the present time the average share held by Great Britain in foreign markets is below 20% while her average share in the imports of empire countries (as later figures will show) is over 40%.

### GREAT BRITAIN'S TRADE WITH THE BRITISH EMPIRE

**Total Exports.**—The extent to which the empire's share of British exports has increased since 1870 is shown in fig. 6. The actual value of the exports is as follows:—

TABLE I.

Total exports of British produce and manufactures and exports to the empire in ten yearly averages 1870-1909, four years' average 1910-1913, and the years 1922 to 1926.

| Year.           | Total export.<br>Millions of £. | Exports to Empire.<br>Millions of £. |
|-----------------|---------------------------------|--------------------------------------|
| 1870-79 . . . . | 218.1                           | 63.5                                 |
| 1880-89 . . . . | 230.2                           | 80.0                                 |
| 1890-99 . . . . | 237.0                           | 79.9                                 |
| 1900-09 . . . . | 333.2                           | 115.8                                |
| 1910-13 . . . . | 474.2                           | 169.6                                |
| 1922 . . . . .  | 361.5                           | 143.5 (140.6)                        |
| 1923 . . . . .  | 390.8                           | 145.2 (141.8)                        |
| 1924 . . . . .  | 398.8                           | 153.4 (150.3)                        |
| 1925 . . . . .  | 398.3                           | 160.2 (156.1)                        |
| 1926 . . . . .  | 356.2                           | 162.7 (159.8)                        |

Note 1.—The Irish Free State which was part of the United Kingdom until 1923 has been omitted from the above figures.

Note 2.—The figures given in brackets in the "empire" column show the purchases of the empire as it was in 1913; i.e., exports to countries such as Palestine, Iraq, etc., which were outside the empire in 1913 have been excluded.

Note 3.—In view of the considerable rise in prices, the post-war figures have for comparative purposes been adjusted to 1913 price levels. No very accurate figures can be given because of the change in the composition of the exports.

Owing to the coal stoppage in 1926 it has been thought necessary to ignore the British trade figures for that year except for illustrative purposes. The fall in coal exports to Europe had the effect of unduly raising the empire share of British exports. The actual increase in the volume of exports to the empire in that year should, however, be noted.

**British Exports to Empire Groups.**—Empire countries may conveniently be divided into five main groups, the Southern, the Indian, the American, the West African and the East African group. Their respective purchases of British goods for the annual average 1911-13 and 1923-25 are shown in Table II.

TABLE II.

| Empire group.          | British exports.             |  |                              |  |
|------------------------|------------------------------|--|------------------------------|--|
|                        | Annual<br>£1,000<br>1911-13. | Average<br>% of<br>total<br>British<br>export. | Annual<br>£1,000<br>1923-25. | Average<br>% of<br>total<br>British<br>export. |
| The Southern group . . | 67,003                       | 13.2   | 110,575                      | 14.8   |
| The Indian group . . . | 69,271                       | 14.18  | 102,540                      | 13.8   |
| The American group . . | 26,333                       | 5.33   | 34,155                       | 4.59   |
| West African group . . | 6,062                        | 1.24   | 11,971                       | 1.61   |
| East African group . . | 1,113                        | .22  | 3,913                        | .52  |

For reasons already given, figures of British exports for the year 1926 have been omitted, but for the first nine months of 1927 the Southern group increased their share of British exports to 16.9% of the total, the Indian group showed a rise to 15.8% a figure above the 1913 level, while the American, West African

and East African groups held shares of 5.2%, 2.0% and .67% respectively.

The first group comprises the three southern dominions—Australia, New Zealand and South Africa. Maintaining very close trading connection with the mother country and capable of almost unlimited development, these three countries together constitute Great Britain's largest empire market. Australia alone is the second largest customer in the world for British goods and her share of the total exports to Great Britain has increased from 6.56% in 1913 to 9.4% for the first nine months of 1927.

The Indian group comprises India, Ceylon, Malaya and the Straits Settlements. India takes more goods from Great Britain than any other country in the world. British export trade to the Straits Settlements, Ceylon and to British Malaya, has expanded considerably in recent years. Together they absorbed in 1924 1.8% of the total export, in 1925 their share had increased to 2.54% and in the first nine months of 1927 to 3.0%.

The American group, of which Canada is by far the most important member, includes Newfoundland, the West Indies and British Guiana. Owing to the immense economic influence of the United States of America upon neighbouring countries, this group is somewhat less affected by the imperial aspect of trade than the other groups in the empire. Canada is, however, an important market for Great Britain, buying per head of population eight times the value of British goods purchased by her larger neighbour.

The West African colonies base their trade upon the native agriculturalist. In East Africa production has so far developed on the basis of the large estate worked by native and Indian labour. Though British East Africa covers a larger area than West Africa, the development of this group of colonies has not proceeded so far, and the export trade with Great Britain is only a third of that of West Africa.

**Total Imports.**—Fig. 7 shows the trend of empire share in British imports. Since 1870 it has risen from 22% to 27%.

Table III. shows the value of imports from the empire 1870–1926.

TABLE III.

Imports of produce and manufactures into the United Kingdom in ten yearly averages 1870–1909, four years' average 1910–13 and the years 1922–26.

| Year.             | Total imports. | Imports from Empire. |
|-------------------|----------------|----------------------|
|                   | Millions of £. | Millions of £.       |
| Av. 1870–79 . . . | 360.5          | 79.5                 |
| " 1880–89 . . .   | 393.6          | 91.2                 |
| " 1890–99 . . .   | 435.8          | 96.8                 |
| " 1900–09 . . .   | 570.3          | 125.9                |
| " 1910–13 . . .   | 717.9          | 179.5                |
| " 1922 . . .      | 659.0          | 188.3 (186.0)        |
| " 1923 . . .      | 712.8          | 195.8 (193.4)        |
| " 1924 . . .      | 792.4          | 217.2 (213.6)        |
| " 1925 . . .      | 824.0          | 248.8 (244.1)        |
| " 1926 . . .      | 846.4          | 236.4 (230.8)        |

Note 1.—The Irish Free State figures have been excluded from the import figures 1923–26.

Note 2.—The import figures given in brackets in the "Empire" column show the post-war consignments into Great Britain from the empire as it was in 1913, i.e., imports from countries such as Palestine, Iraq, etc., have been excluded.

Note 3.—Post-war values have been adjusted to the 1913 price level.

#### COMPLEMENTARY AND COMPETITIVE TRADE

From the middle of the last century, manufacturing activity became the distinguishing mark of the economic life of a constantly growing number of nations. During and since the World War the output from the world's factories has been tremendously increased and Great Britain is meeting increasingly serious competition in all the markets of the world. As a result, those countries which are to-day taking Great Britain's manufactures and sending in exchange raw materials for her industries and foodstuffs for her urban population are essential to her welfare. Thus a most important aspect of empire trade is its complementary nature as opposed to the competitive trade which characterizes

the interchange between Great Britain and those countries which are her industrial rivals.

**Composition of British Exports to the Empire.**—The Board of Trade classifies British external trade under three main heads:—

- (1) Food, drink and tobacco.
- (2) Raw materials and articles mainly unmanufactured.
- (3) Articles wholly or mainly manufactured.

Great Britain, as a predominantly manufacturing nation, with most of her skill and capital locked up in highly specialized in-

FIG. 7.—PROPORTION OF BRITISH IMPORTS FROM FOREIGN AND EMPIRE COUNTRIES FROM 1870 TO 1926

dustries, must be especially interested in the extent of markets overseas for the third of these classes. From the standpoint of national social welfare, it is the output of highly manufactured goods requiring the employment of the highest degree of national skill which should be encouraged. In 1925 the empire was responsible for only £5,568,000 or 11% of the total export of coal from Great Britain. Of manufactured goods, however, in this year £284 millions or 46.1% was exported to the empire, and in 1926 empire countries took as much as half of Great Britain's total manufactured exports. The export trade pillars given herewith, show the value of exports in each of the three classes to empire countries and to foreign countries for the annual average 1911–13 and 1923–25.

**Composition of British Imports from the Empire.**—The pillars shown below give the value and proportion of each class of imports supplied by the empire and by foreign countries for the annual averages 1911–13 and 1923–25.

It should be pointed out that a considerable proportion of the empire imports classed as manufactured consists of semi-manufactured metals, the raw materials of many British industries.

The relative importance of empire supplies of certain essential foodstuffs and raw materials is shown in the following figures:—

|  | Empire share of imports in 1925. | Value of Empire imports 1925. |
|--|----------------------------------|-------------------------------|
|  | %                                | £ mill.                       |
| Wheat and flour . . . . .                | 56.0                             | 42.8                          |
| Beef . . . . .                           | 13.1                             | 4.8                           |
| Mutton and lamb . . . . .                | 59.0                             | 13.5                          |
| Butter . . . . .                         | 48.0                             | 25.5                          |
| Fruit (fresh dried and canned) . . . . . | 25.5                             | 11.3                          |
| Wool . . . . .                           | 83.0                             | 63.0                          |
| Hides and skins . . . . .                | 47.0                             | 10.2                          |

## TRADE OF THE OVERSEAS EMPIRE

**The Southern Group: Australia.**—Australia, among the three dominions in the southern group, maintains the largest volume of imports and exports. The following table shows the extent of Australian trade with empire countries:—

AUSTRALIAN TRADE: ANNUAL AVERAGES

|                            | 1911-13<br>(ooo's omitted.) |             | 1924-26<br>(ooo's omitted.) |             |
|----------------------------|-----------------------------|-------------|-----------------------------|-------------|
|                            | £                           | % of total. | £                           | % of total. |
| Imports:                   |                             |             |                             |             |
| Total imports              | 74,958                      | ..          | 149,797                     | ..          |
| Imports from Great Britain | 37,729                      | 50.4        | 66,165                      | 44.2        |
| Imports from Empire        | 46,249                      | 61.6        | 85,816                      | 57.4        |
| Exports:                   |                             |             |                             |             |
| Total exports              | 79,034                      | ..          | 143,360                     | ..          |
| Exports to Great Britain   | 33,841                      | 42.6        | 58,734                      | 41.0        |
| Exports to Empire          | 47,898                      | 60.5        | 74,950                      | 52.2        |

Australia's trade with empire countries, apart from Great Britain, amounts to a little over one-tenth of the total. India and New Zealand are the chief participators in this trade.

Though Great Britain takes about the same proportion of Australian produce as she did in the pre-war years, her share in Australian imports shows a decline. This decline is partly attributable to a post-war increase of non-competitive imports into Australia from the United States of America, such as petrol, but also to the growth of foreign competition, which is reducing the British share of the import trade of almost every country in the world. It should, however, be remembered that whereas British exports are only about 80% of their pre-war volume, the volume of Australian imports from Great Britain is greater than it was before the World War.

The chief Australian exports are wool and wheat, the former representing in 1926 40.7% of Great Britain's total imports of wool.

**New Zealand.**—Of the three southern dominions, New Zealand, though the volume of her trade is not so great as that of either Australia or South Africa, maintains the closest touch with the trade of Great Britain and other empire countries.

NEW ZEALAND TRADE: ANNUAL AVERAGES

|                            | 1911-13<br>(ooo's omitted.) |             | 1924-26<br>(ooo's omitted.) |             |
|----------------------------|-----------------------------|-------------|-----------------------------|-------------|
|                            | £                           | % of total. | £                           | % of total. |
| Imports*:                  |                             |             |                             |             |
| Total imports              | 20,933                      | ..          | 50,291                      | ..          |
| Imports from Great Britain | 12,533                      | 60.0        | 23,868                      | 47.5        |
| Imports from Empire        | 17,306                      | 82.8        | 36,056                      | 71.8        |
| Exports:                   |                             |             |                             |             |
| Total exports              | 21,261                      | ..          | 51,050                      | ..          |
| Exports to Great Britain   | 16,708                      | 79.0        | 40,405                      | 79.0        |
| Exports to Empire          | 19,956                      | 94.3        | 44,422                      | 87.0        |

\*Imports are classified according to "Countries of origin" in 1924-26, and according to "Countries of consignment" in 1911-13.

There can be no doubt that New Zealand trade is considerably greater than in pre-war years. According to figures published by the New Zealand Government, taking 1900 as the base year at 1,000, the volume of New Zealand trade in 1913 was 1,341 and in 1924 1,835. A large proportion of New Zealand's inter-empire trade is conducted with Australia.

New Zealand is predominant in the empire as a supplier of butter, mutton and lamb to the British market. Export figures are available since 1905 showing the increasing predominance of products derived from the grasslands of the dominion. In 1905 69.8% of the exports from New Zealand were pastoral in origin, and in 1924 this proportion had increased to 94.2%. Though wool is the chief export, yet the development of dairying has been mainly responsible for the marked rise in these percentages. Great Britain now relies upon New Zealand for 20% of her import requirements of butter in comparison with 5.6% pre-war, and of the total imports into Great Britain of mutton and lamb New Zealand holds 55.5%.

**South Africa.**—The following table of South African trade shows that Great Britain holds a slightly larger share of South Africa's import trade than she does of imports into either Australia or New Zealand. There has been, however, a decline in the volume and proportion of South African exports going to countries within the empire due to a diversion of South African produce from the United Kingdom to European countries, particularly France and Germany.

SOUTH AFRICAN TRADE: ANNUAL AVERAGES

|                            | 1911-13<br>(ooo's omitted.) |             | 1924-26<br>(ooo's omitted.) |             |
|----------------------------|-----------------------------|-------------|-----------------------------|-------------|

| Imports from Great Britain | 21,754                      | 57.0        | 30,805                      | 48.6        |
| Imports from Empire        | 25,737                      | 67.3        | 39,886                      | 63.0        |
| Exports:                   |                             |             |                             |             |
| Total exports              | 60,699                      | ..          | 74,466                      | ..          |
| Exports to Great Britain   | 55,137                      | 91.0        | 45,766                      | 61.5        |
| Exports to Empire          | 55,577                      | 91.8        | 59,729                      | 80.5        |

South Africa's chief exports are gold, wool and diamonds. The South African gold output amounts to 50% of the world's total production and nearly 80% of her export goes to Great Britain.

**The Indian Group: India.**—The following table shows the extent of Indian trade before and since the war and the share

FIG. 8.—COMPOSITION OF BRITISH EXPORTS TO EMPIRE AND FOREIGN COUNTRIES DURING THE PERIODS 1911-1913 AND 1923-1925

held by Great Britain and the rest of the empire. The original Indian trade figures have been converted from rupees to £ sterling at the average rate of exchange ruling during each year.

INDIAN TRADE: ANNUAL AVERAGES

|                            | 1911-13<br>(ooo's omitted.) |             | 1924-26<br>(Year ending March.)<br>(ooo's omitted.) |             |
|----------------------------|-----------------------------|-------------|---|-------------|
|                            | £                           | % of total. | £   | % of total. |
| Imports:                   |                             |             |   |             |
| Total imports              | 107,203                     | ..          | 174,668   | ..          |
| Imports from Great Britain | 67,883                      | 63.5        | 89,093  | 51.0        |
| Imports from Empire        | 74,623                      | 69.9        | 102,720   | 58.5        |
| Exports:                   |                             |             |   |             |
| Total exports              | 157,193                     | ..          | 263,174   | ..          |
| Exports to Great Britain   | 39,032                      | 24.8        | 59,221  | 22.5        |
| Exports to Empire          | 62,839                      | 40.0        | 96,792  | 36.8        |

The extremely close trading connection established between India and the home country is thrown into relief if Great Britain's share of the imports of another eastern market—namely, China—is noted. In 1925 Great Britain's share of Chinese imports amounted to only 9.8% of the total as compared with 51% in the case of Indian imports.

The disproportion between the empire percentage of Indian imports and exports needs some explanation. Indian exports to

empire countries, other than Great Britain, are marked by a considerable trade in jute goods to Australia and New Zealand and by a more general trade, of which cotton piece goods form a large proportion, to Mauritius and the Straits Settlements. Australia, in years when there is a failure in the Indian wheat crop, sends consignments of wheat to India.

**Malaya.**—One of the most dramatic episodes in the development of empire trade has been the growth of the wealth of Malaya through the introduction (via Kew Gardens) of the para rubber tree from Brazil and the increase of the exports of tin. Per head of her population Malaya is now one of the largest exporting countries in the world. Great Britain shares in the import trade of the Straits Settlements to the extent of less than 10%, but the empire share as a whole is over 50%, India and the Malay States being mainly responsible. The low share held by Great Britain in this market is due to the fact that almost all food for the Straits Settlements has to be imported.

**The American Group: Canada.**—The growth of Canada's export trade between 1911-13 and 1924-26 as shown by the table below is an unmistakable index to the rapid development of that country. Taking figures for the latter period and adjusting them on the basis of 1913 price levels, Canadian exports have actually doubled in volume. Canada has become the premier wheat exporting country in the world, and the number of motor-cars which she exports is second only to the United States of America.

The United States is naturally Canada's chief source of supply. It is, however, of interest to note that Great Britain holds twice as large a share of the Canadian market as she does of the market provided by the United States of America. A feature of Canadian trade with the empire during the last few years has been the considerable growth in the exports to and imports from Australia. Since the year ending March 1925 the value of imports from Australia has more than doubled, while Australia has increased her purchases by over 50%.

**West Indies.**—The trade between Canada and the West Indies is an important inter-empire development. In June 1920, a reciprocal arrangement was entered into with the West Indies and, in 1925, this agreement was enlarged. It seems probable that the mutual tariff advantages so arranged will lead to Canada becoming an increasingly important source of supply of manufactures and foodstuffs to the West Indies and a valuable market for their tropical products, chiefly sugar and bananas.

**Newfoundland.**—The import trade of Newfoundland, similarly to that of Canada, is greatly affected by the United States of America. The share of the mother country in Newfoundland imports in 1925 was 31%, but in 1926, probably largely owing to the stoppage of consignments of coal, it had fallen to 21%. Of the Newfoundland exports 30.4% went to Great Britain in 1925 and 23.5% in 1926. Empire supplies (largely from Canada) accounted in 1925 for over 70% of the total, and exports to the empire accounted for 43% of the total. Newfoundland exports a limited range of products the most important of which are dried fish, cod liver oil and paper pulp.

**West African Group.**—The West African group is composed of the following colonies and protectorates: Gambia, Sierra Leone, Gold Coast (which includes British Togoland) and Nigeria (which includes British Cameroons).

Territorial alterations since the World War make any general comparison between pre-war and post-war years difficult, but the direction of Nigerian trade is indicative of the trade of the other West African colonies.

| Exports to Empire          | 3,326                       | 53.0           | 9,192                       | 57.6           |

Nigeria is the only important country in which Great Britain has increased her share of the total imports since pre-war years. The inter-imperial trade of West Africa, apart from that with Great Britain, mainly consists of trade between the several West African colonies. Foreign trade plays quite an insignificant part in West African economic life.

The typical West African exports are oilseed and palm oil. Practically 50% of the total value of Nigeria's consignments abroad are accounted for by these two staple articles of export. During recent years there has been an important development of the cocoa industry especially on the Gold Coast. This colony exports nearly half the total cocoa of the world.

**East African Group.**—Kenya and Uganda, representing the bulk of British East African trade, provide the best basis for comparison between pre-war and post-war years. Since April 1, 1917, these two colonies have been amalgamated in one customs union and for the purpose of foreign trade are treated as a single unit. The trade figures for 1911-13 are given on the same basis.

TRADE OF KENYA AND UGANDA: ANNUAL AVERAGES

| Exports to Great Britain   | 147                         | 48.9           | 3,338                       | 50.0           |
| Exports to Empire          | 527                         | 61.5           | 5,429                       | 81.5           |

Though close trading connections exist between Great Britain and East Africa, eastern markets have a considerable influence. A significant feature of the post-war trade is the immense increase of exports to India. The Indian share of the exports of Kenya and Uganda in 1911-13 was 4.2% and in 1926 it had risen to 17.8%. Imports from India had increased from a pre-war share of less than 2% to a share in 1926 of 10.2%.

Uganda is becoming of considerable importance to the empire as a supplier of cotton. The total exports of cotton have increased from 90,000 bales in 1922-23 to 180,000 bales in 1926. In 1926 Kenya coffee represented 30% of the total supplies sent to Great Britain and 80% of the empire grown supplies.

**Irish Free State.**—A review of empire trade would be incomplete without some mention of the new commercial position of the Irish Free State and the extent of the trade of this dominion. From April 1, 1923, Southern Ireland became an independent economic unit. In 1926 the Irish Free State was the fifth most important market for British goods. For the annual average 1924-26, 79.3% of her total imports valued at £64,000,000 were of British origin and 97.4% of her total exports valued at £45,000,000 went to Great Britain and Northern Ireland. The great bulk of Irish trade thus proceeds through British ports. Owing to the Irish import and export figures showing countries of con-

signment rather than of origin or final destination, the extent of her trade with countries other than Great Britain cannot be accurately estimated.

#### SUMMARY OF EMPIRE TRADE POSITION

Since 1913 the trade of India and of the great four dominions has, with the exception of that of South Africa, grown in importance in relation to the rest of the world. Their imports and exports as percentages of world imports and exports in 1913 and 1925 were as follows:—

|                        | 1913<br>% | 1925<br>% |
|------------------------|-----------|-----------|
| India . . . . .        | 3.60      | 3.78      |
| Canada . . . . .       | 2.78      | 3.65      |
| Australia . . . . .    | 1.99      | 2.43      |
| South Africa . . . . . | 1.37      | 1.19      |
| New Zealand . . . . .  | .54       | .83       |
|                        | 10.28     | 11.88     |

In 1925 the empire as a whole shared in world exports to the extent of 30% of the total.

In the immediate post-war years, the United States of America and Japan made serious inroads into many empire markets but, by 1923, British trade had largely regained the lost ground. During the last three years, however, competition has increased and the United States is substantially increasing its sales to empire countries. The special importance of empire trade to the dominions and India is shown by the fact that in every case, except Canada, about 50% or over of the total is carried on within the empire.

As to the actual volume of inter-imperial trade—apart from its distribution—statistics indicate that the self-governing dominions and India have suffered from the general depression following the war. In most cases there has been an actual loss of purchasing power and, except in the case of New Zealand and

of primary producers. The consolidation of the economic position of the dominions has not affected the principle of the preferential tariffs granted to British goods entering dominion markets, the average preference given by the dominions being 4% in 1913 and 9% in 1923.

It is possible that the next decade will see a growing recognition in Great Britain of the importance of the empire and an increasing prosperity based upon a great development in the purchasing power of the dominions and of such groups of colonies as those in West and East Africa. It must be anticipated that, with the growth of secondary industries in the dominions and India, Great Britain will need to cater to an increasing degree for a demand for more highly manufactured goods.

#### FINANCE

Before considering each dominion by itself, certain broad facts must be stated. Each unit of the empire imposes and collects its own taxes, and is free to use the proceeds for its own needs. No taxes collected in a dominion or Crown colony come to the British exchequer. A dominion is free to borrow money where it likes, but is encouraged to come to London by the fact that its loans rank as "Trustee Securities" in Great Britain, and so command a better price. A dominion is free to maintain such tariffs as is thought necessary, even against Great Britain. Imperial defence is primarily the burden of the United Kingdom, and while the dominions take their share in it, the apportionment is a matter of informal arrangement rather than rigid law.

**Canada.**—The unit of currency is the Canadian dollar, equivalent in value to the U.S. dollar at \$4.866 to the pound sterling. British sovereigns are legal tender, but in practice never emerge from the banks. The export of gold was restricted during and after the World War, but has been free since June 30, 1926.

The currency in circulation consists of dominion and bank notes. Dominion notes are based on the following support:—

- \$50,000,000 against a 25% gold reserve.
- \$26,000,000 against securities, including \$16,000,000 in certain guaranteed railway securities.
- Any excess must be mainly against 100% gold reserve, but this provision is modified by the Acts of 1914 and 1923.

The circulation in June 1926 was \$175,712,915, or \$18.49 per head. Gold reserves amounted to \$94,999,481, or 54%, and securities to \$80,713,434.

Notes are also issued by the leading Canadian banks, but in "normal times" these are not legal tender. A bank may issue notes equal in amount to its paid-up capital without a gold backing, and during the period of crop movements may issue "excess" fiduciary circulation to the amount of 15% of its combined capital and rest or reserve fund, but must pay 5% interest on this excess. Any further issue must be backed fully by gold or dominion notes deposited in the central gold reserve. The average circulation for 1926 was \$168,885,995, against paid-up capital of \$116,638,254, reserves of \$125,441,700 and gold and dominion notes amounting to \$5,790,572.

The present banking system originated from the needs of the Montreal traders and has a history of rather more than a century behind it. Unlike the United States, it is based upon the branch banks; the 11 chartered banks, most of them possessing their head offices in the east, between them cover the country. No attempt is made to segregate the country into districts, as is done

FIG. 9.—COMPOSITION OF BRITISH IMPORTS FROM EMPIRE AND FOREIGN COUNTRIES DURING THE PERIODS 1911-1913 AND 1923-1925

Canada, exports also have declined. Each succeeding year, however, brings reports of increased trade. A close analysis of the inter-empire trade of each empire group yields many encouraging signs.

The period since 1911 has been for the dominions one of consolidation. The closure of many foreign and imperial markets during the war caused attention to be turned upon the internal economic position, and the outcome has been a desire for a better balanced production. This object is being sought by means of tariffs to encourage secondary production and by the organization

by the Federal reserve system in the States. The Canadian banks have been compared, with some justice, to the Scottish banks. Clearings and general supervision are conducted by the Canadian Bankers' Association, which has certain statutory powers. Wheat being the country's most important article of export, the main banking problem is the financing of crop movements during the season and the employment of the surplus funds released during the remainder of the year. As the Canadian money market is relatively small, the bulk of free money is lent on call, not in Toronto or Montreal, but in New York. The ebb and flow of this call money naturally swamps the normal "text-book" influences acting upon the rate of exchange.

Geographical influences and the Canadian tariff have led to the investment of large quantities of American capital in Canada, and many industrial undertakings are under American control. The foreign capital invested in Canada in 1926 was estimated to aggregate over \$5,000,000,000, in the ratio of three to two as between the United States and Great Britain, all other countries together representing less than 10% of the total. On the other hand there are considerable Canadian investments abroad, in Newfoundland, the West Indies and in Latin America, the income from foreign investments being estimated at from \$30,000,000 to \$40,000,000 annually. The total estimated national wealth of the country was estimated by the Dominion Bureau of Statistics at Ottawa at \$22,482,841,122 in 1920. The gross national public debt for the year ended March 31, 1926, was \$2,821,209,462, without deduction of over \$440,000,000 represented by active assets, sinking funds, advances to provinces, investments, etc. The greater part of the Dominion, provincial, and municipal securities is held in the Dominion itself, which, as it develops, also shows an increasing ability to finance its own business itself. The total value of the dominion field crops for 1927 was estimated at over \$1,000,000,000 (£200,000,000), the value of other farm products being \$700,000,000; the corresponding value of the industrial output was estimated at \$3,000,000,000.

**Australia.**—The fundamental fact about Australian finance is that it is that of a new and rapidly developing country. While customs and excise are reserved to the Commonwealth Government, the individual States have definite powers with regard to other forms of taxation. Australia is the only country whose income tax is based upon a progressive curve, defined by the incorporation of the principles of the differential calculus in an act of parliament.

The currency is the pound sterling, and sovereigns are coined but not put into circulation. The actual currency in use consists of notes issued by the Commonwealth Bank, which are legally convertible. Normally the currency exchanges at par with British currency, but when the gold standard was suspended in Britain after the war, the rate of exchange moved away from parity and in accordance with trade demands. In actual practice the Commonwealth Bank is the chief buyer and seller of exchange, and so used to fix the rate from time to time. The variation from parity was a source of some inconvenience and loss to traders in both countries, and for a time there was a demand for a unified empire currency; but with the restoration of the gold standard in the United Kingdom, the anomaly ceased and the demand fell in abeyance.

The rapid development of Australia, added to its war expenditure, has necessitated the frequent raising of loans and many of these are obtained in the London market. On June 30, 1927, the aggregate debt of the Commonwealth and Federal States was, according to the *Statist*, £1,016,000,000, of which £518,000,000 had been borrowed internally, £478,000,000 in London and £20,000,000 in New York. Much of this money is represented by remunerative assets, such as railways, harbours and other public works, so that the total debt cannot be called excessive nor can it be compared with the national debts of older countries, which represent mainly past and unremunerative expenditure. Notwithstanding this fact there was during post-war years an impression in London that Australia was over-borrowing. This was largely due to the fact that at that date the Commonwealth and each separate State had independent borrowing powers, with the result that frequently one Australian loan came hard on the

heels of the last. The obvious remedy was co-ordination, and in 1927 an important practical step was taken in the creation of a Federal Loan Council for the purpose of financial co-operation. It is the duty of this council to ascertain the needs of the constituent members and the amount that can be borrowed without undue disturbance; the Commonwealth and the member States will be rationed accordingly. All future loans are to be issued by the Commonwealth Government, except that the Loan Council can sanction State loans, to be issued under the guarantee of the Commonwealth. The Commonwealth has further agreed to take over the State public debts, expected to aggregate £8,635,445 for the financial year 1927. At the end of 1927 the formal adoption of the scheme still depended upon an amendment to the Constitution.

Australia is in one sense well provided with banks, but in 1927 the demand for accommodation had outstripped the resources available. Hence, in addition to amalgamations, many of the banks were increasing their capital in order to obtain fresh funds to meet the demand for loans. This operation was rendered easy by the high return so obtaining on existing bank shares. There are several large banks in the country, and there is no tendency among them to limit their operations to a single State; many of the banks, too, have London offices and are firmly established in New Zealand.

**New Zealand.**—Financially, New Zealand is closely linked with Australia, and the fundamental economic conditions are much the same. As regards currency, bank notes form the chief medium of circulation. These are issued by the two New Zealand banks and also by the four Australian banks who carry on business in the country. Notes must be backed to at least one-third in gold held in New Zealand, while the remaining two-thirds can be covered in British, Australian or New Zealand securities. The unit is the pound sterling, and while the export of gold is permitted, the notes are inconvertible inside New Zealand.

The fact that Australian banks operate in New Zealand means that the banking relations between the two countries are very close, and they may be studied together. The banker's problem is that of the banker in every pastoral and agricultural country, namely, how to finance the farmer through the season and how to employ the surplus funds during the rest of the year. In 1926 the Bank of New Zealand was concerning itself with the problem of long-term loans on mortgage to agriculture.

Like the other dominions, New Zealand is a familiar figure in the London loan market. In 1925, her obligations were £118,000,000 borrowed in London and £104,000,000 raised internally. Since that time the national public debt has enlarged somewhat, but as an offset to it the Dominion Government owns revenue-producing assets valued at above £200,000,000.

**South Africa.**—From the standpoint of pure finance South Africa stands out in sharp distinction from the rest of the empire. From the fact that the bulk of the world's gold is produced here, gold circulates to some extent inside the Union and gold shipments therefore possess a different significance; gold, in fact, must be regarded as one of the staple products of the country, and its relation to the money and exchange markets judged accordingly.

Possibly the most important event in South Africa's financial history since the union is the foundation of the South African Reserve Bank which was set up in 1921. It resembles in many respects an American Federal Reserve Bank, is principally a bank of issue and possesses the sole right to issue notes, this right expiring in 1946. It has a capital of £1,000,000, of which £300,000 is held by other South African banks, each of whom is bound to hold shares to an amount equal to 5% of their own paid-up capital. Its dividends are limited to 10%, and any surplus profits have to be allocated to reserve. When the reserve fund equals the paid-up capital of the bank, all surplus profits go to the State. The board of directors consists of representatives of the Government, and of banking, industry, commerce and agriculture. Its reserve regulations are also modelled on the Federal reserve system. The note issue must be covered as to 40% in gold, and as to the remainder in approved "commercial paper" or bills of exchange representing genuine trade transactions. All

deposits lodged with a bill payable by the bank must also be covered by 40% in gold. Finally, every South African bank is bound to carry a balance at the reserve bank equivalent to 13% of its own demand deposits and 3% of its time deposits. The Union Government does its own banking business through the reserve bank.

The unit of currency is the pound sterling, and since the restoration of the gold standard in Great Britain, the exchange has been at par. Even before the foundation of the reserve bank, banking in the Union was well developed. Possibly the leading bank is the Standard Bank of South Africa, whose head office is in London. This was founded in 1862 and now operates all over the Union, and also in east, central and west Africa; it also has a holding in the Bank of British West Africa.

Like the other colonies South Africa is a well-known borrower in London, where South African loans command a high reputation. At the end of March 1927 the national public debt stood at £231,476,000; but of this total 77% may be classed as productive, being investment in State railways and other revenue producing enterprises. Of the total debt £147,810,000 has been raised externally (which means almost exclusively in London), leaving nearly £84,000,000 held internally. A different class of security, even more familiar on the London Stock Exchange, are South African mining shares. London stock-brokers are many of them more conversant with labour and other working conditions on the Rand than with similar conditions at home. The gold from the Rand reached a new peak of production in 1927 with 10,130,630 oz.; taking the price of gold at 85s. per oz. this represents a value of £43,055,178.

**India.**—Financial conditions in India are governed by several imponderable factors. The first is the fact that India is not one homogeneous nation, but consists of 20 or 30 peoples. Another is that gold and silver are the traditional form of wealth, and their accumulation is stimulated by definite religious beliefs and ceremonies; hence the absorption of the precious metals by the Indian population. Superimposed on these is the influence of London as the chief financial and trading link between India and the outer world. Thus in India the modern complexities of trade and exchange exist side by side with the most primitive methods, and the banking, currency and financial system has to take account of both.

The unit of currency is the rupee, consisting of 165 grains of fine silver. Until 1893 its exchange rate was fixed by the price of silver, and in effect it represented nothing more or less than this definite weight of silver. The trend of silver values and other forces led, however, to a gradual but marked modification of the currency system. First the "silver exchange" was replaced by the gold "exchange standard." Silver could no longer be tendered by the public, to be coined into rupees, and the British sovereign and half sovereign were made legal tender at the rate of R.15 to the pound sterling. Also the Government undertook to sell "council drafts," drawn upon its balance in India, at a maximum rate of rs. 4½d. per rupee, and in case of need "reverse councils" drawn on London if and when the exchange rate fell below rs. 3½d. Thus by law and practice the rupee was valued at rs. 4d.; if it began to vary from this point the Government could contract credit by selling "reverse councils" which had to be paid for in rupees, or expand credit by selling "councils" and so releasing rupees. Furthermore, the Government managed to educate the people to the point where it could get notes into circulation; these notes were convertible and had a definite backing behind them in the "paper currency reserve."

The World War upset this system because it temporarily made the bullion value of the rupee greater than rs. 4d., and so made it a paying proposition to melt rupees down, and because the Government found they had not enough rupees at their disposal to meet the public demand for councils. After the armistice an attempt was made to fix the rupee at R.10 to the gold sovereign, but this broke down almost at once owing to world-wide deflation and the temporary dislocation of Indian trade. In 1926, a definite gold standard was adopted. The par of exchange was fixed at rs. 6d. to the rupee, and the Government is bound to buy or sell

gold or gold exchange at this rate, save that it cannot be made to deal in less quantities of gold than 1,065 tolas. The present exchange system is much the same as that ruling in England to-day.

Banking in India is also a complicated matter. On the one hand there are many small native banks, often differing very little from the money-lender or money-changer of time immemorial, while on the other hand there are the big exchange and other well-known banks, centred in Bombay, Madras or Calcutta, but by no means confining their activities to those cities. First among these come the Imperial Bank of India, established by law in 1920 to take over the business of the three former Presidency banks; it has over 150 branches, acts as the banker of the Government, and performs most of the functions of a central bank. In particular its rate of discount sets the financial tone for the whole of India. It has no note issue. In 1927 the supremacy of the Imperial bank was threatened by the proposal to establish a new reserve bank, to become the official and *de facto* central bank, and to buy and sell gold and gold exchange in the place of the Government, which now performs this function. The proposal failed to become law.

Dealings in foreign exchange are conducted mainly by the big eastern exchange banks, who virtually form the Bombay, Madras and Calcutta markets. Foreign trade is mainly financed through London, either by sterling bills, or by rupee bills covered by an appropriate purchase or sale of sterling in London. Much of the trade with America is financed by rupee bills, and dollar bills are few and far between. Originally, most of India's capital needs were provided for in London, and Indian Government loans and railway stock still maintains a leading place on the London Stock Exchange, and command a high degree of confidence; like other empire securities, they also possess special facilities to qualify as "trustee stocks." But with the growth of industry India is now also beginning to provide for her own capital needs. At March 31, 1926, the national public debt was £342,000,000 held in Great Britain and R. 5,112,700,000 internal debt.

**Crown Colonies, etc.**—The finance of the Crown colonies, dependencies and other portions of the British empire, though of less importance than that of the dominions, is not without interest. To remove a misapprehension fairly general in some quarters, it should be said at once that each colony runs its own finance, collects its own taxation and pays it into its own exchequer, and so long as it pays its way, is financially independent of the British treasury. To quote what is perhaps the leading example, the proceeds of the export duties upon rubber, imposed as the effective instrument in the Stevenson restriction scheme, go to swell the revenues of the Crown colonies concerned, and not those of Great Britain.

As regards currency, too, each unit is independent: Singapore and Hong Kong have each their own dollars; Tanganyika has its shilling, and so on. Kenya, in particular, has had a chequered currency history. Immediately after the war the Indian rupee was in circulation, and so Kenya shared in the attempt to raise the rupee from 15 to the pound to 10 to the gold sovereign. Next, a florin was introduced, and held at 10 to the pound even after the new rupee parity had been tacitly abandoned. For a time this gave rise to serious inequities, and it is only with the general currency stabilization of the past few years that an equilibrium has been established.

Most of the Crown colonies are too small to need a central bank of their own, and to a large extent they are served by branches or subsidiaries of banks domiciled in Great Britain or one of the dominions. Instances of this are the Standard Bank of South Africa and the Bank of British West Africa, as cited above; while the Far Eastern colonies, such as Hong Kong and Singapore, are served by the big eastern exchange banks. (N. E. C.)

#### COMMUNICATIONS

The first line of communication of the empire is by sea. Until the outbreak of the World War the great majority of the ships serving empire ports were owned by companies operating from the British Isles, but during the war and immediate post-war periods,

the dominions, notably Canada and Australia, developed mercantile marines which largely operate on empire routes. About 400,000 gross tons of shipping engaged in overseas trade were actually owned by these dominion Governments in 1925, but whilst they assisted trade development they were also a cause of substantial losses. The losses have become so serious that efforts are being made in some cases to dispose of the fleets. These government-owned fleets had at first an advantage in immunity from taxation, but at the Imperial Conference of 1923 it was agreed that liability to taxation should be the same as for privately owned vessels.

Liner routes steadily increased after 1910, and in 1926 there were 560 such routes from the British Isles. Not all were empire routes, but there was at least one, and frequently more than one, liner route connecting Great Britain with each of the dominions and colonies, whilst there was a marked development in the organization of lines working directly between the overseas dominions. An effect of this was to give greater stability to freight rates, but also to make them less flexible. Sea carriage remained the cheapest form of transport. In 1925 it cost only 1d. to bring 1 lb. of meat from Australia to Great Britain; ¼d. per quarter for wheat from Canada or ¾d. from Australia, and 3/20d. per lb. for rice from Rangoon.

Freights are, however, subject to considerable variation, due to changes in the balance of cargoes on the routes at different times and seasons. The serious drop in coal exports from Great Britain during the post-war period caused British shipping to be less remunerative and kept up freights for the carriage of raw products to Great Britain. The Australian trade is, from a shipping standpoint, unusually well balanced. The worst balanced route is that across the Atlantic to Canada and Newfoundland, for the United Kingdom exports to Canada and Newfoundland mainly manufactured goods, occupying moderate cargo space in relation to their value, and imports grain, timber, pulp, flour, and other comparatively bulky goods. A notable development, particularly after the war, was the growth of direct trade of the dominions or colonies with one another. The Imperial shipping committee, founded in 1920, has materially assisted in the co-ordination and standardization of practice within the empire.

British ships of 8,000 tons and upwards increased from 214 at the end of 1913 to 395 at the end of 1925, whilst the records of 1926 show that 46.9% of the British tonnage consists of such ships. With the growth in the size of ships the need for deep water ports and for dock equipment which would provide for a rapid turn round of the ship was emphasized. The outcome was a marked tendency for the traffic to pass through a limited number of ports. Though the Board of Trade publish returns for over 100 ports in Great Britain, the bulk of the traffic passes through 14 or 15 of them, while London and Liverpool together handle over 50% of the total. Taken as a whole, the Empire is well provided with ports with a depth of water of 35ft. upwards, or with ports which can readily be deepened as soon as the necessity arises. The tendency, however, has been to develop a large number of ports, and this often compels ships to call at several to ensure a full cargo. New Zealand perhaps suffers from this more than any other part of the empire, which accounts for freights being relatively high.

A new development is the institution of "cabin-class" steamers. The White Star Line and the Canadian Pacific are running a number of these steamers. The fares are about ⅔ the usual first-class fares. Already a large increase in the number of people exchanging visits between Great Britain and Canada has resulted.

**Railways.**—The railway systems of the various parts of the empire differ very much in their adequacy. In the majority of cases they are in the hands of the state, and, whilst in some cases they are worked to cover all expenses, in others there is an annual deficiency incurred for national development. With the growing belief that such a deficiency should not continue indefinitely, the plan of transferring the railways to a state company, or having a railway budget independent of the national budget, has won an increasing amount of support. The Union of South Africa led the way, whilst Canada followed in 1917 when the Canadian National Railways Co. was created; and India in 1925, when the recom-

mendations of the Acworth commission were adopted. These changes should make for a more even and economic development of railways in the dominions, with material advantages to trade. In India they are leading to more rapid developments also. Lack of standardization seriously hindered the development of railway communication in Australia, each state having decided its railway gauge without regard to its neighbours, but steps are being taken to remedy this. In the Crown colonies the prospects of improving the supplies of raw materials within the empire largely depend upon railway development.

**Roads.**—The rapid strides made in motor vehicles are increasing the importance of road transport. Due to the development of six-wheeled and trackless vehicles, it is possible also to carry on transport for moderate distances over tracks and earth roads. By opening up country at distances from the railway, these vehicles are speeding up development, enabling the railways to become paying concerns more quickly, and so make extensions.

**Air and Wireless Services.**—In the speeding up of transport, the biggest prospect comes from the development of air transport. In 1925 its possibilities were limited, particularly by the difficulties of night flying. For communication with Great Britain, its uses were restricted to the carrying of passengers or mails for a terminal stage of the journey. A day, for instance, might be gained on the India mail by use of the aeroplane service to Paris and Marseille, and a saving of 15 days made by the air service from Cairo to Baghdad for the London mails. If airship services should develop, the times necessary for mails to reach the East or Australia would be cut about two-thirds. In 1925 the only direct wireless service of an empire character was that between the United Kingdom and Canada, which had been in existence since 1907, though a limited service with India was maintained by way of Egypt. The first suggestion for an empire wireless scheme was made in 1911, and had it not been for the war this would probably have been put into operation. Afterwards a question arose whether the Marconi company or the Government should carry out the scheme in Great Britain. Eventually a decision in favour of the Post Office ownership and operation was reached, though the Marconi company was employed for the construction of the high power station at Hillmorton, near Rugby, which was opened on Jan. 30, 1926. This station is used for broadcasting the Government bulletin and other purposes, but is no longer part of the general imperial scheme, now carried out on the short-wave beam system. This system is now working directly with Australia, Canada, India and South Africa, with such success that the charges for messages have been heavily reduced. In spite of great improvements made by the cable companies, the latter are losing ground. To avoid cut-throat competition, a fusion of interests has been agreed upon.

## EDUCATION

**Imperial Education Conference.**—In 1907 a number of educational administrators from parts of the British empire, who were attending in London an educational congress convened by the League of the Empire, met representatives of the home Government and suggested that an official Imperial Education Conference should be convened periodically by the British Government. The Government of the day adopted this suggestion and through the Board of Education convened the first such Conference in 1911. The delegates were nominated by the several Governments of the Empire, being either heads of education departments or persons officially connected with their educational administration. The Conference recommended that meetings should be held at intervals of four years, but the war caused the second meeting to be postponed to 1923; the third was held in 1927.

The first Conference had 51 members and met for a week; the second had 62 members and met for a fortnight; the third had 95 members and took three weeks to complete its business. On each occasion there were delegates from the self-governing Dominions, India, the Crown Colonies, Dependencies, etc. In 1927 the Mandated Territories were also represented.

The work of the Conference may be divided into two parts. Firstly the movements of teachers and students about the Empire give rise to a number of rather technical problems best solved after personal discussion between responsible officials. Thus when a teacher migrates it is necessary to determine his professional status, his salary, etc., in his new country. Migrant students bring with them problems as to the equivalence of examinations for the purpose of admission to training colleges, universities and other institutions for higher education. The Conferences have endeavoured to devise principles to be applied in the solution of such problems. Their recommendations have resulted in legislation directed to the facilitation of movement and thus to the promotion of imperial unity.

Secondly, attention is given at each meeting to educational problems of the moment on which the experiences of each country are likely to be helpful to all. Thus in 1923 a description of the correspondence tuition methods by which the Australian education departments reach children in remote homesteads led to the adoption of similar methods in other parts of the Empire. The 1927 Conference discussed the use of wireless broadcasting in education, while in both 1923 and 1927 the educational possibilities of the cinema were explored.

The 1911 Conference established an Advisory Committee to carry on its work between successive Conferences. It consists of the accredited agents in London of the several Governments concerned, presided over by the secretary of the Board of Education, and has made the arrangements for the later Conferences and advised on questions referred to it by the education departments at home and overseas. It conducted, for example, certain inquiries into the working of the scheme for the temporary exchange of teaching posts at home and in the Dominions, and investigated the possibility of a common form for the display of the fundamental statistics of public education in all the countries of the Empire.

An official report of the proceedings at each Conference is published by H.M. Stationery Office. (J. H. B.)

### AUSTRALIA

Education in Australia is administered and controlled separately by the six States; only in the territories of central and northern Australia and in the Federal capital area of Yass-Canberra is the Federal Government responsible. Education in the Northern and Central territory is organized with the help of the Queensland Education Department, whilst New South Wales takes charge of Canberra on behalf of the Federal Government.

In every State one of the foremost problems is that of the "out-back" children, the families of settlers in sparsely populated districts living miles from any school or any railway connecting them with a school. Various efforts have been made to meet their needs. Itinerant teachers have been sent out to visit each family four times a year and enable the children to pursue home studies with such help as their families can give. This method, however, is gradually being abandoned as transport facilities improve and State grants enable the children to travel to the nearest school or board in hostels. Further, a successful system of correspondence tuition, even for young children, is developing. Correspondence pupils win scholarships and are able to continue their education beyond the primary course. There are also "provisional schools" with a very small attendance, where the building must be provided locally. Another expedient for the rural child is the "subsidized school" where two or more families join to engage the teacher, and the Government makes a grant of £5 per pupil towards the salary. South Australia takes the palm in the provision for rural needs, for there a school may be established where only six children are gathered together. G. S. Browne (*Education in Australia*) stresses the value of a highly centralized system of administration in a "young country with a vast hinterland. It ensures that the chil-

dren of the rural pioneer receive as good an education as the children of the banker or artisan in the city." That is, indeed, hardly possible, but clearly more local autonomy can come only as the population increases and localities become equal to the greater burden.

**Primary Education.**—Education in all Australian States is free and compulsory. As in England, it was originally left to the voluntary efforts of the Churches, and there are still a number of denominational schools of all grades unaided by the State. The most important denominational endowed schools closely correspond in character to the English public schools.

In New South Wales, Victoria, Western Australia and Queensland, education is compulsory between the ages of 6 and 14, in South Australia between 7 and 13, and in Tasmania between 7 and 14. In some cases pupils may leave earlier if they reach the requisite standard. In Victoria children are admitted at four and a half and in Queensland at five. In some infant schools kindergarten (*q.v.*) and Montessori (*q.v.*) methods are used. Victoria is the only State using Montessori apparatus for mental defectives. In South Australia the Government makes grants to the free kindergartens of the Kindergarten Union, which have adopted Montessori methods; there are also Montessori-kindergarten classes in the State schools for children under six. Western Australia has no State infant schools, but there are free kindergartens established by the Free Kindergarten Union. There are also "opportunity classes" for backward children set up jointly by several schools. In all six States school medical and dental services are developing.

**Religion and the Schools.**—The relation of the State to private Church schools varies somewhat from State to State. In New South Wales State aid to other than State schools was abolished in 1883. By the Act of 1916 private schools may enjoy State inspection and recognition, and they may then receive pupils holding State bursaries, which are many and generous under the Bursary Endowment Act of 1912. In State schools there is "general religious instruction as distinguished from dogmatical and polemical theology," subject to a conscience clause. Recognized religious teachers may enter the schools to instruct children of their own denomination. The registration of private schools is compulsory in Victoria and Tasmania. Non-sectarian religious instruction is given in State schools in all six States. Queensland, Western Australia and Tasmania allow denominational instruction before or after school hours by ministers and accredited religious teachers to children of their own faith.

**Secondary Education.**—As an agricultural country, and one which is likewise developing its own industries, Australia has devoted attention to agricultural and technical education as well as to the more academic secondary course. She has also made special provision for the children who will not stay at school beyond the age of 15 or 16. The very liberal system of State bursaries and scholarships makes it possible for the majority of children to receive at least some secondary education, and for those of more than average ability to climb the educational ladder from the primary school upwards to courses at the universities. This is also a means of securing the efficiency of schools not under State control, for they may, with the approval of the Minister, be registered and thus enable their pupils to hold State bursaries and scholarships. Unregistered schools do not receive grants from the State.

All the States maintain high schools; fees have been abolished in New South Wales, South Australia, Queensland and Western Australia. In New South Wales there are "superior public schools" for twenty or more pupils who are prepared to take a two years' post-primary day continuation course. Victoria has supplementary courses at primary schools for children from 12 to 15, and in the metropolitan areas central schools with a two years' high school syllabus. There are domestic arts schools for girls from 12½ to 14, and junior technical schools admitting to a three years' course at 12. Both continue the general cultural education of the pupils. Some schools have experimented with the Dalton system (*q.v.*), some with marked success, and with school councils where the children perform certain functions of self-government. Class A schools have been allowed to substitute internal tests (with cer-

tain safeguards) for the usual external examinations, and these tests are recognized by the university. South Australia has central schools with a domestic, technical and commercial course in addition to continued general education. The more gifted pupils may proceed at 15 or 16 to the upper divisions of the high school. In 1921 higher primary schools were started in the small towns. The secondary course is four years, or five in the largest schools. The Technical Education of Apprentices Act makes three years' attendance at a trade school for half a day and one evening per week compulsory for apprentices in most skilled trades in "proclaimed areas." Queensland has secondary departments to primary schools, known as "topped schools." The State is in process of taking over the technical colleges and transforming them into technical high schools, where technical and general education are combined. Attendance at technical classes is compulsory for apprentices. Western Australia has central schools with a two years' course, vocational and cultural. In 1918 post-primary correspondence classes were started for children "outback." Some schools have adopted the Dalton plan. In Tasmania pupils may pass at 13 from the primary school to a high school or technical school with a four or five years' course, and thence to the university. There are junior technical schools on the Victorian model, and trade technical schools for apprentices with a four years' course.

There is a strong movement towards abolishing the pupil teacher system and making a minimum standard of secondary education the condition of admission to the teachers' training colleges. In Victoria and Western Australia would-be teachers serve as monitors or junior teachers before entering the college in order to test their suitability for the work. The outlying country schools have suffered from insufficiently trained teachers, but some States are making a term of service in the country a condition of promotion in the city schools. The registration of teachers is compulsory in Victoria and Tasmania.

**Higher Education.**—The universities of Sydney and Melbourne (*see also* UNIVERSITIES) stand very high among the universities of the empire and have faculties of world-wide reputation. They have considerable endowments and receive like the universities in each of the other Australian States governmental aid but without control. The universities are in the main non-residential, but there are attached hostels which are usually established and managed by various religious denominations. Each State supports agricultural colleges with experimental farms and South Australia has a school of mining with a high reputation. The Workers' Educational Association (*q.v.*) is active in Australia, on lines similar to those in Great Britain, receiving State grants and co-operating with the Universities. (M. M. G.; A. P. N.)

*See* G. S. Browne, *Education in Australia* (1928); *Year Book of the Commonwealth of Australia*.

### CANADA

By sec. 93 of the British North America Act (1867), the control of education in the Dominion was exclusively entrusted to the provinces and a special safeguard was added that no law passed should prejudicially affect any right or privilege with respect to denominational schools that was legally possessed by any class of persons in the provinces at the time of confederation. The safeguard involved a principle of great importance, for Canadian educational systems derive from two separate ancestries and there is much opportunity for difference over religious matters. The undenominational system of English-speaking Canada has been founded on English and Scottish precedents modified by American experience, while the system of the Roman Catholic Church, in which religious instruction, according to its tenets, forms a vital part, prevails in French-speaking Quebec.

The beginnings of education in Quebec date back to the efforts of the missionaries under the French régime, when certain religious communities established schools, but there was no definite organization, and it was not until 1836 that assistance was first granted by the State. In 1841 a Department of Education was set up for the united provinces of Upper and Lower Canada, and in 1846 an act was passed by the provincial legislature establishing the basis of the modern school system. The supreme education author-

ity for the province of Quebec is a council of public instruction with two sides supervising the Roman Catholic and Protestant schools respectively. The Catholic committee includes the bishops and vicars apostolic of the province, with 15 laymen nominated by the provincial ministry. The Protestant committee is composed of 15 clergy or laymen who are similarly appointed. Each committee has independent jurisdiction over the schools of its own faith, but questions of common interest are decided by the council as a whole. Each committee is assisted by co-opted associate members who are chosen for their special educational experience and represent the interests of the teachers. Subject to the general approval of the provincial Government, each committee makes regulations for the organization, administration and discipline of the schools, their inspection and examination and the training of teachers. The superintendent of public instruction, who is *ex officio* president of the council, is assisted by two deputy heads, called the French and English secretaries of the department, who are responsible for their respective sides. Save in the cities of Montreal and Quebec the province is divided into school districts in each of which there is a school board elected by the local ratepayers and serving for three years. Where there is a religious minority, they may establish schools of their own governed by elected trustees. The cost of education is defrayed from three sources: provincial grants, local rates assessed on all property within the school district and fees paid by parents having children of school age. In Montreal there are appointed school boards and the rates assessable are fixed by the provincial legislature. In the Protestant and Jewish elementary schools of Montreal there are no fees, but in the Roman Catholic schools, as elsewhere throughout the province, fees are charged and are collected with other school rates. The teaching in the Catholic schools is mostly conducted in French, and the methods differ considerably from those of the Protestant schools, which are similar to those of the English-speaking elementary schools in the rest of Canada. A considerable amount of the teaching in the Catholic schools is entrusted to members of religious communities, and the Church exercises a close control. Most of the teachers in the Protestant schools receive a professional training in normal schools, or in the departments of education at McGill university, or the Anglican Bishops' college at Lennoxville.

Secondary education in the province of Quebec is divided upon even more sharply marked denominational lines than primary. The most distinctive institutions on the French side are the residential classical colleges with almost wholly clerical staffs. Boys enter them between 12 and 14 and receive a classical training on traditional lines until they have taken their *baccalauréat* and pass on to the professional schools at Laval or Montreal university. There are also various "independent schools" for boys and girls, carried on by communities of friars and nuns respectively, but all are subject to inspection by the Catholic committee of the council of public instruction. The number of Roman Catholic non-residential secondary schools provided by local school boards is increasing and they are supported by government grants, local rates and fees in the same way as the primary schools. The most ancient educational institution in the province is Laval university, in the city of Quebec, which has developed from the seminary for education for the priesthood, founded in the middle of the 17th century. An affiliated institution has in recent years become well endowed and has become the university of Montreal. In each of these universities the courses are organized on professional lines and the methods of instruction derive from the precedents of the ancient university of Paris.

The educational system of English-speaking Canada finds its fullest development in Ontario, but in its essentials it is the same in all the provinces. In each there is a Department of Education presided over by a provincial minister, but the routine administration is in the hands of permanent officials of the civil service. At their head stands a deputy minister or superintendent, who has a large share of responsibility for educational efficiency throughout his province. There are inspectors appointed and paid by the Government, but in Ontario those in charge of the primary or "public" schools are appointed locally. The settled parts of the

provinces are divided into school districts, each with a board of trustees charged with the duty of equipping and maintaining both primary and secondary or "high" schools. The primary schools are mainly undenominational, but in Ontario and Manitoba the Roman Catholic minority is permitted to maintain separate schools. Religious teaching of a simple kind is permitted in the undenominational schools, with the safeguard of a "conscience clause." In the past there has been considerable political difficulty in certain provinces over the questions of religious and language teaching, and on more than one occasion the "schools question" has led to cases before the courts which have been carried to the judicial committee of the privy council, on appeal, for an interpretation of the constitutionality of certain acts passed by the provincial legislature.

The primary schools are organized in "grades" corresponding roughly to English "standards," and education is free and compulsory for all children between the ages of eight and 14. In Ontario either full or part-time attendance is now required up to 16, and in some cases up to 18, a requirement that has greatly increased the attendance in the secondary schools of the province. Increasing attention is being paid to technical and vocational work for the older pupils who do not pass on to the university. In the larger cities, industrial, technical and art schools have seen a great development in recent years, and everywhere throughout Canada great attention is paid to agricultural education in schools and colleges, ranging upwards from farm schools to elaborately equipped and staffed agricultural colleges with experimental farms attached. Certain of the Canadian agricultural colleges rank among the best in the world. Secondary education in Government-aided schools is free throughout English-speaking Canada, but there are, in addition, certain boarding schools of high reputation modelled on the lines of an English public school. Of these the most celebrated is Upper Canada college at Kingston, where generations of those who have proved to be the leaders in Canadian life have been educated.

In Western Canada an acute and pressing difficulty faces the provincial Governments in providing for the education and assimilation of the many immigrants from Central and Eastern Europe who have come to settle since the beginning of the 20th century. The problem of providing schools and teachers for these immigrants has been a great burden on the Prairie provinces, and it cannot be said that it has yet been satisfactorily solved.

The universities of Canada have been greatly influenced by the vast developments that have taken place in the universities of the United States within the last 50 years. The two leading institutions—Toronto and McGill (Montreal), represent different types in the organization of their finances, the first being supported by public funds like the State universities in the republic, and the second depending upon its endowments like the British universities. They differ little, however, in their academic organization or curricula. To the first type belong the new universities of the West: Manitoba, Saskatchewan, Alberta and British Columbia, while in the East most of the universities belong to the second type, the best known of them being Queen's (Kingston, Ontario), and Dalhousie (Halifax, Nova Scotia). Laval (Quebec) and the University of Montreal have already been mentioned as differing considerably from other Canadian universities in organization and curricula. (See UNIVERSITIES.)

For statistical details reference may be made to the official *Canada Year Book*, published annually (Ottawa) and to the *Annual Survey of Education in Canada*, prepared in the Education Statistics Branch of the Dominion Bureau of Statistics. Brief accounts of the history of Canadian education may be found in *Sixty Years of Canadian Progress* (Ottawa, 1928), and A. P. Newton, *The Universities and Educational Systems of the Empire* (1922). For current information concerning Canadian universities, see *The Universities' Year Book*, published by the Universities' Bureau of the Empire. (A. P. N.)

### INDIA

The problems of education in India are immense with the immensity of that vast peninsula. There is, moreover, this perplexity, that, whereas in most countries education is linked continuously through all grades and stages, in India a deep rift divides higher education from primary. Higher education uses

English as its language-medium: education for cultivators and artisans is necessarily in the mother-tongue, and India's millions speak in many vernaculars. Further, higher education is relatively widespread and advanced, while something like nine-tenths of the whole population remain illiterate. Yet another difficulty comes from ancient prejudice against the education of women. It is no longer true that figures for female education are negligible, but custom and prejudice still seriously obstruct every effort to advance the education of India's womanhood.

Nevertheless, the sum total of organized education is very considerable. There are now 14 universities in British India, without counting Rangoon, Mysore and Osmania. All aspire to be teaching as well as examining universities: in some there are the promising beginnings of research, the most extensive organization for the purpose being found in Calcutta. Studies have approximately the same scope and range as those of European universities, but in most cases a faulty examination standard detracts from their efficacy. English is, for the most part, the medium of instruction; imperfect mastery of this medium is a great stumbling-block. University students in 1926 numbered 87,589, some 1,500 of these being women.

Secondary education is widely diffused and the demand for it does not slacken: but far too much of this education is narrow in aim, dull and mechanical in method. The true use and value of the school as an institution are imperfectly recognized. Even among High English schools, which lead to the universities, there are few in which school life is as full and vivid as it may be. The school aim has been unduly restricted: these schools do not educate for life, but prepare candidates for university matriculation. It is, however, fair to recognize that strenuous efforts have been, and are being, made in the right direction. There is also now a tendency towards the substitution of the vernacular for English in teaching. In 1926 the total number of Secondary schools, higher and lower, Vernacular and English, was nearly eleven thousand. The number of pupils was not far short of two millions, all but 174,000 being boys. Pupils in primary schools in 1926 numbered nearly eight millions. Yet this is only about a fifth of the number of children who might have been at school, and there is small ground for contentment with the advance made in recent years, though that has been substantial. This failure does not come from want of recognition of the greatness of the need. It has been affirmed again and again in Government declarations of policy. The hindering causes have been, the absence of any popular demand, scarcity of teachers, want of money, unwillingness to impose special taxation to provide it. These hindrances remain: nevertheless, opinion is moving definitely towards making elementary education compulsory, and at the same time free: practical steps in this direction are being taken in many places. Much may be hoped from the delegation of the responsibility for primary education to local authorities—municipalities for towns, and district boards for rural areas.

Technical education is backward, but efforts to make good deficiencies are unremitting, the recent development of training schools for railway employees being one significant advance. Professional education is fairly well developed. For teaching, zealous and successful work is being done in training colleges and normal schools. Law colleges are amply provided. Medical education is increasing, but is still very inadequate to the needs of the community; engineering progresses but slowly; notable success attends the School of Forestry at Dehra Dun; veterinary colleges are doing useful work.

The machinery of education is variously controlled. The universities are self-governing, but receive some financial help from Government. High school education is at present controlled mainly by the universities, but there is a movement for placing high schools under the control of boards set up for the purpose. Primary and secondary education are both under the supervision of Government inspectors. Schools are staffed and equipped by missionary agency or private enterprise, largely with the help of grants-in-aid. Government also maintains and manages directly a few schools of all types, to set the standard. In every province there has been since 1854 a highly organized education depart-

ment, the activities of which touch every branch and kind of education.

The total spent on education in 1926 from public sources was over £9,000,000. There is considerable expenditure from missionary, municipal, and private funds, in addition; and some from endowments.

**History.**—For about 40 years after Warren Hastings founded the Calcutta Madrasa (1781), British interest in Indian education was confined to the encouragement of the traditional Islamic and Hindu learning, and the funds first assigned to education in 1813 were devoted to that purpose. A definite change of policy came in 1835, the date of Lord William Bentinck's "Resolution" and Macaulay's "Minute," which together determined that from that time on the main line of educational advance should be through "English education." But the beginnings of English education go back 20 years earlier, and came, in effect, in answer to a popular demand, and out of the belief that a true revival of learning in India could most effectually be brought about by means of the English language. The Hindu College, Calcutta, was founded in 1817 under the inspiration of this belief. In 1854 the despatch of Sir Charles Wood formulated a comprehensive scheme of education for all India, the groundwork of the present system. Progress since that time has been continuous. There have been three principal epochs, each following the appointment of an Educational Commission. The first of these was in 1882 and resulted in an immense extension of high school and college education. The second, the Universities Commission of 1902, was occupied with university reform, at that time much needed. The third, in 1917, remembered as the Sadler Commission, dealt exhaustively with the problems of higher education in Bengal, including schools. Its recommendations embody sound educational principles, but, so far, it has only been found possible to apply some of them practically, and these not in Calcutta University. Quite recently (May 1928), an "auxiliary committee" in connection with the Simon committee has been appointed to inquire into the growth of education in India.

**Retrospect and Outlook.**—The aims of the education fostered under British control in India were from the first philanthropic, looking to the hope of intellectual and moral renewal. They have been criticized as too narrowly practical—the training of useful subordinates for the public services. They have also been criticized as misdirected and impractical. To the diffusion of western learning through English there was reasoned opposition from the first, and there has been intermittent criticism since, because of the inevitable conflict between modern thought and Indian life and tradition. The bitterest and most damaging attacks on the educational system have come from men who owe the effectiveness of their weapons largely to the system which they denounce. For these critics the ground of quarrel is that English education in India demoralizes and denationalizes. Whatever truth there may be in these criticisms it remains beyond dispute that the great educational experiment launched by the Despatch of 1854 was well-intentioned, and that its results have been on the whole beneficent. One striking result has been the attainment by the Indian peoples of a common language in which to express their political aspirations. But the strongest title of the existing system of education to favourable judgment is that it has been the effective cause and motive power of a true Indian renaissance. This revival permeates Indian society very widely. It takes three main forms: (1) the revival of vernacular literatures and of Indian art; (2) social reform; (3) political developments. One of the political developments is that the control and guidance of educational policy is passing from British into Indian hands; and this is the really salient feature of the present time.

It is early yet to estimate the effects of this transfer of education to Indian ministers. In their political aspects, these are the subject of the enquiry of the auxiliary committee mentioned above. The stumbling block since 1919 has been the financial stringency; but there has been a quickening of public interest in education, which may have far-reaching results. There is, however, the danger that educational interests may suffer eclipse amid the excitements of party politics. This would be a great misfortune,

for all who reflect and reason acknowledge that the new political ideals in India depend for their progressive realization on education.

(H. R. JA.)

Coatman, chap. viii. pp. 315-333 (Calcutta, 1928); Syed Mahmood, *A History of English Education in India, 1781-1893* (1895); F. Andrews, *The Renaissance in India* (1912); J. Ghosh, *Higher Education in Bengal under British Rule* (Calcutta, 1926).

#### NEW ZEALAND

The first mission school in New Zealand was established in 1816. An ordinance of 1847, recognized and allotted financial assistance to religious schools for both whites and Maoris, but this remained inoperative as regards whites. The Act of 1871 established village Maori schools with local committees on which both races might serve.

The Act of 1877 made education free, compulsory, and secular. This statute is the keystone of the present system. Though education is secular, the door is opened to religious instruction for those who desire it by the fact that permission may be given to use school buildings for other purposes out of school hours. Under this act the country was divided into districts, each with an education board to administer grants, establish and maintain schools and training colleges, and appoint teachers. School committees for small areas are elected by the householders, and these committees in turn elect the boards, besides managing their own schools under the board. Each secondary school, however, is managed by its own governing body. The whole system is placed under the control of a central department of education, over which the minister of education, a member of the cabinet, presides. Later acts have made the registration of private schools compulsory, set up a teachers' register, and obliged all teachers, in public and private schools, to take the oath of allegiance.

**Primary Education.**—New Zealand, like the other dominions, has its problem of the isolated rural child, and provides correspondence classes as well as free conveyance to school. Itinerant and organizing teachers are sometimes employed to staff the small "back-block" schools, while of recent years the consolidated school has become popular wherever established. The Act of 1914 fixes the age of compulsory schooling from 7 to 14. In addition to primary schools proper there are so-called district high schools, established where there are not enough children for a separate secondary school, and these unite primary and post-primary departments. In 1926 there was approximately one primary school to every 500 of the European community. In sparsely populated areas there are part-time schools, so that one teacher can take charge of two schools.

Schools are shared by whites and Maoris, but where the Maoris are still living a primitive, tribal life they have their own village schools or attend mission schools. The Government also reserves free places for Maoris at certain denominational boarding schools. Its aim is to assimilate the Maoris to the life of the white population. The Health Act of 1920 gives authority for the medical inspection of primary school children. Dental clinics are being provided.

**Secondary Education.**—Government secondary schools were set up under the Act of 1914, but there were at that time already certain first-rate endowed secondary schools modelled on English public and grammar school lines. District schools, as already stated, combine primary and secondary departments. Under the act of 1903 free places were provided in endowment secondary schools and district high schools. Indeed New Zealand is remarkably generous in this matter. At the end of 1925 96% of the scholars in Government secondary schools held free places. Technical high schools are recognized as being of secondary grade. The Act of 1924 established junior high schools for children unable to stay at school for the full secondary course.

**Adult Education.**—The University of New Zealand was recognized in 1876 as an examining body with affiliated colleges in the University of Otago (Dunedin), Canterbury college (Christchurch), Victoria college (Wallington) and Auckland were added later. In 1925 a royal commission on university education was appointed, and some of its recommendations were incor-

porated in the Act of 1926, which made the university a teaching body embracing its four affiliated colleges (*see also* UNIVERSITIES). The Workers' Educational Association (*q.v.*) co-operates with the university and receives a Government grant.

Teachers' training colleges in New Zealand provide a two years' course, or one year for university graduates. The department keeps a graded register of certificated teachers.

With a total white population of 1,346,076 on December 31, 1925, the numbers at school and college were:—

|                      |         |
|----------------------|---------|
| Primary . . . . .    | 248,248 |
| Secondary . . . . .  | 23,829  |
| Technical . . . . .  | 12,966  |
| University . . . . . | 4,494   |
| Total . . . . .      | 289,537 |

### SOUTH AFRICA

The history of education in South Africa has been a chequered one owing to the long political troubles that delayed union. In Cape Colony and Natal English precedents were generally followed, while in the Orange Free State and the Transvaal the educational system was largely influenced by the pastors of the Dutch Reformed Church. Since 1902, however, the systems of primary education have approximated more closely and development in all four provinces of the Union has proceeded on parallel lines. Since the white population of South Africa is bi-lingual, the language difficulty in the schools has sometimes been acute. The questions raised by the education of the native and coloured population differ widely from those in connection with the education of the white population and are separately considered (*see* section, Native Education, above).

The South African Act of 1909 made higher education a matter for the Union Government, which might subsequently take over other branches left, for the time being, under the provincial governments. The Union Government did, in fact, take over technical and vocational education in 1925, including the industrial schools for neglected and indigent children and those removed from undesirable surroundings. These and the trade schools give pre-apprenticeship training in skilled trades, and, in the words of the report of the Secretary for Education, the Hon. Dr. D. F. Malan (1925) "a suitable standard of civic education and general culture must be aimed at."

The report of the Education Administration commission of 1923 made some important recommendations, including greater co-ordination under the Union Government. It advocated free primary education; those who could not pay should be admitted free to Government secondary schools, and ability to learn, not to pay, should be the sole test of admission to those schools.

Only in Natal is educational administration centralized. In the Cape there are local school boards with a majority elected by the ratepayers and a minority appointed by the Government. The Smuts Act of 1907 set up local school boards and school committees in the Transvaal. In the Orange Free State the Hertzog Act of 1908 established local committees elected by the parents, which in turn elect district boards. Afrikaans (*i.e.*, South African Dutch) and English are equally recognized. Children are taught at the outset in their mother tongue, but learn the second language at a later stage.

**Primary Education.**—Primary education is separately managed in the four provinces and is everywhere free. In the Cape and the Orange Free State it is compulsory for white children from 7 to 16, in Natal and the Transvaal from 7 to 15. But there are regulations allowing children to leave younger if they have completed standard VI. and are in regular employment. These regulations were condemned by the 1923 commission, which pointed out that the brightest children, who would profit most by prolonged schooling, were deprived of it early, whilst slow and dull pupils remained, a drag on their juniors, making profitless efforts to reach the required standard. The commission recommended that no child should leave before 15, and that the slower children should be allowed to remain in the primary school till 16 and complete the primary course. All four provinces have school medical services.

Throughout the Union undenominational religious teaching is given, subject to a conscience clause, but only in the Cape is denominational teaching allowed in State schools under certain conditions.

Like Australia, South Africa has its problems of children living in such isolation that school attendance is impossible. The Government makes grants to "farm schools," that is, groups of children gathered at a farm under the guidance of a governess or tutor.

**Secondary Education.**—In the Transvaal and Orange Free State secondary education is free in the State schools; in Natal only bursars and the dependants of those on active service are admitted free. Grants are made to private secondary schools. The needs of the country children are met by attaching secondary standards to some of the primary schools and providing hostels and transport. There are plentiful bursaries and scholarships.

South Africa has universities at Capetown, Stellenbosch and Witwatersrand, besides the University of South Africa consisting of six constituent colleges with headquarters at Pretoria, and six technical colleges (*see also* UNIVERSITIES).

**Native Education.**—Native education is largely in the hands of religious bodies, receiving State grants. In the Transvaal the Smuts Act of 1907 provided for separate native schools, and in the Orange Free State progress has been made with the provision of native schools. Natal, likewise, has special schools for native coloured and East-Indian children, and does not admit them to the schools for whites.

The South African Native college was founded in 1915. It is maintained by Government grants, denominational funds, and fees, and it presents students as external candidates for the examinations of the University of South Africa.

### NATIVE PEOPLES

The well-being and development of the subject peoples of the British empire (who, outside India, Canada, Australia and New Zealand, number 68,000,000) demands a systematic, purposive education by means of schools. Incomplete statistics (1926) show about 1,800,000 non-Europeans enrolled in 52,000 institutions (ranging from simple village schools to university colleges) in British Africa, and 800,000 in similar institutions throughout dependencies and mandated territories. Christian missionary societies have been the pioneers of native education. In 1917 Dr. Charles T. Loram could say: "It is entirely due to the efforts of the missionaries that the Natives of South Africa have received any education at all, and to this day all but three of the several thousand native schools are conducted by missionary agencies." Apart from the 28,900 Mohammedan schools in Nigeria this is true of nine-tenths of the educational institutions throughout British Africa. In recent years more general interest has been taken in the subject, particularly as regards Africa, owing to a fuller realization of (1) the implications of Trusteeship, (2) the necessity of arresting the disintegration of social life consequent upon the impact of western civilization, and (3) the need of training the natives to co-operate with Europeans in developing the rich resources of the country and in other important activities.

In Africa great developments followed the tours of the two Phelps-Stokes commissions (1920, 1924). While cordially acknowledging the value of what the missions had done the commissions criticized some of their methods. The Cape of Good Hope had, since the time of Sir George Grey (1854), assisted mission schools with grants-in-aid, but most of the other administrations, through lack of funds if not lack of will, had done little or nothing for education. These now listened readily to sane and disinterested men who urged that education was the key to the welfare of the Africans. Since 1924 they have thrown considerable energy into the task.

In 1923 an advisory committee on native education in tropical Africa was set up by the British Colonial Office. Its scope was afterwards extended to include other dependencies. The committee formulated principles which the Imperial Government accepted as the basis of future action. In brief, the policy is one of collaboration with the missionary societies. The general direction of educational policy and the supervision of all schools are reserved to the administrations. Advisory boards, representative of both parties (and in some cases, of settlers) have been set up, new codes adopted, directors of education appointed, and an earnest effort is being made to raise the standard of education. In particular great attention is given to the training of teachers, including "Jeanes" supervisory teachers on the American model. In addition to opening more schools of their own the administrations in tropical Africa have greatly increased their grants-in-aid. Their expenditure on native education grew from £250,000 in 1921 to £650,000 in 1926. In the latter years the Governments in British Africa (including the Union) spent £1,250,000 in this way; those in dependencies outside Africa spent about £800,000. This does not include the £500,000 devoted to the Prince of Wales College at Achimota on the Gold Coast.

Crude as it might be in the absence of schools and books, pagan Africans and other peoples had their own system of training the young to take their place in the tribe. The new education too, in Africa especially, is conceived and planned with direct and conscious reference to the needs of the community. The aim is to produce, not imitation Europeans but better Africans, by fostering the growth of a culture suited to the African genius and reflecting the African spirit. The advisory committee declared that "education should be adapted to the mentality, aptitudes, occupations and traditions of the various peoples, conserving as far as possible all sound and healthy elements in the fabric of their social life; adapting them where necessary to changed circumstances and progressive ideas, as an agent of natural growth and evolution." Such an education further implies, as Sir G. Guggisheim has pointed out (Franco-British Congress, July 1928), the enabling of the native to "make full economic use of the lands, products and industries of the country." It should therefore pay careful attention to African music, art, folklore and history as the basis and groundwork of the whole, and also to the vernacular, both as a subject and a medium of instruction. The multiplicity of languages raises a problem of enormous difficulty, especially in the provision of literature. The difficulty is partly met by employing, for educational purposes, certain expansive languages such as Swahili in East Africa. Technical and vocational training is given largely in Government workshops and offices. Handwork is taught in schools as an essential part of education and as a means of improving the conditions of native life. Stress is laid on agriculture and hygiene, for it is recognized that schools offer a first class instrument for promoting the health and prosperity of the community. In everything it is chiefly the formation of character that is aimed at. The inflooding of civilization has tended to the decay of old sanctions of morality, the sapping of old loyalties. Governments agree with missions that if education is to be formative it must be religious. In Mohammedan areas provision is made for the teaching of Islam; in pagan areas definite encouragement is given to Christian teaching.

**BRITISH EMPIRE EXHIBITION:** see EXHIBITION AND TRADE FAIR.

**BRITISH HONDURAS**, formerly called *Belize*, or *Balize*, a British crown colony, bounded N. and N.W. by the Mexican Territory of Quintana Roo, N.E. and E. by the Bay of Honduras; S. and W. by Guatemala. Area 8,600sq.m., including about 212-sq.m. of cays. The frontier, defined by conventions of 1859 and 1893 with Guatemala, ascends the Sarstoon from the Bay of Honduras for about 25m. as far as the rapids of Gracias a Dios, and thence, turning northward, runs in a straight line to Garbutt's

rapids on the Belize. From this point it proceeds due north to the Mexican frontier, where it follows the Hondo to its mouth in Chetumal bay.

Approach to the coast is through the islets known as cays, and through coral reefs, and is both difficult and dangerous. For some miles inland the ground is low and swampy, with mangroves and tropical jungle. Next succeeds a belt of rich alluvial land, seldom more than a mile in width, beyond which, and parallel to the rivers, are extensive tracts of sandy, arid land called "pine ridges," from the trees (*Pinus cubensis*) with which they are clothed. Further inland comes the less elevated "broken ridge" country, of mixed scrub. These tracts are intersected by what is called "Cahoon ridges," with a deep rich soil covered with myriads of palm trees and broad savannas, studded with clumps of trees which are threaded by streams from the mountains. The latter rise in a succession of ridges parallel to the coast. Nearest to Belize (the capital) are the Manatee hills, from 800 to 1,000ft. high; beyond these the Cockscomb mountains rise to 3,680ft. Sixteen streams, large enough to be called rivers, descend from these mountains to the sea, between the Hondo and the Sarstoon. The uninhabited country between Garbutt's rapids and the coast south of the Cockscomb mountains consists of pine ridge and open grasslands, with fine pasturage in the west and valuable forests in the east. Its elevation varies from 1,200 to 3,300ft. Auriferous quartz and traces of other minerals have been discovered, but not in workable quantity. The geology, fauna, and flora resemble those of Central America (*q.v.*). Although within the tropics, the climate is subtropical. The highest shade temperature recorded is 98°F., the lowest 50°. Easterly sea-winds prevail most of the year. The dry season lasts from mid-Feb. to mid-May; rain occurs at intervals during the other months, and almost continuously in October, November, and December. The annual rainfall averages about 81½ in., but rises in some districts to 150 in. or more. Malaria fever is endemic and other tropical diseases occur sporadically, but the country is not unhealthy in comparison with the West Indies or Central American states.

**Inhabitants.**—British Honduras is a little larger than Wales, and has a population of about 47,900 (estimated 1927). Pure-bred white inhabitants number less than 1 in 25; the remainder are of mixed descent. The majority are hybrids of negro slaves, native Indians, and white settlers. There are (1) Maya Indians, chiefly in forest villages in the west and north, away from the sea; (2) descendants of English buccaneers, mixed with Scottish and German traders; (3) the woodcutting class known as "Belize creoles," of more or less pure descent from African slaves or labourers, from the West Indies; (4) the Caribs of the south, descendants of the population deported in 1796 from St. Vincent, of mixed African and Carib origin; (5) in the south, a Spanish-Indian population, from Guatemala and Honduras; and (6) in the north, a Spanish-Indian group which came from Yucatan in 1848. The population increases steadily; about 45% of the births are illegitimate and males are more numerous than females. Many tracts of uninhabited land and forest were once thickly populated. The country abounds in ruins of the ancient Maya civilization. The most important, at Lubaantun, are (1927) being systematically explored on behalf of the British Museum.

**Natural Products.**—British Honduras has long depended on timber, especially mahogany, logwood, cedar, and dye-woods and cabinet woods, such as lignum-vitae, fustic, bullet-wood, santamaria, ironwood, rosewood, etc. The coloured inhabitants are unsurpassed as woodmen and neglectful of agriculture, so that there are less than 50,000ac. of tilled land. Sugar-cane, coconut palms, bananas, plantains, and citrus fruits are cultivated; vanilla, sarsaparilla, sapodilla or chewing-gum, rubber, and the cahoon or coyol palm, valuable for its oil, grow wild. The government has established a forest department, administered by a board of trustees, with a view to conserving and replanting the most valuable kinds of timber. Most encouraging results have attended the experimental treatment of a defined reserve. A concession has been granted for the exploitation of about 300sq.m. of Crown pine-forest by means of the bleeding of turpentine and preparation of lumber for export.

**Chief Towns and Communications.**—Belize, pop. (1927) est. 12,600, the capital and principal seaport, is described in a separate article. Other towns are Stann Creek (2,500), Corosal (6,756), Orange Walk (1,200), Punta Gorda (926), the Cayo (500), Monkey River, and Mullins River. All these are administered by local boards. Telegraph and telephone lines connect the capital with Orange Walk and Corosal in the north, the Cayo on the western frontier, and Punta Gorda in the south. There is a light railway for about 25m. up the Stann Creek river valley, built at public expense for a banana trade which has failed. There are no metalled roads except in or close to the principal towns. A graded earth road from Belize to the northern district is under construction. The principal means of communication are the steamers which ply along the coast and motor boats on the navigable rivers. Mail steamers from New Orleans, Liverpool, Colon, and Puerto Cortes in Honduras, regularly visit Belize.

**Commerce and Finance.**—The average annual value of imports (chiefly cotton goods, breadstuffs, hardware, beer, wines, spirits, and groceries) for five years to 1925 was £775,185, of which £614,815 was entered for home consumption, £160,370 for re-export. The average annual value of exports during the same period was £657,220, of which £305,760 was colony produce and £351,460 transit trade and re-exports. Forest products make up 78% of the domestic exports (mahogany and cedar £196,915, chewing gum £34,780, logwood £5,000). Agricultural products made up 20% (coconuts £32,540, bananas £25,000). In 1894 the American gold dollar was adopted as the standard coin. Government notes are issued to the value of 1, 2, 5, 10, 50, and 100 dollars, and there is a local currency of one cent bronze pieces, and of 5, 10, 25 and 50 cent silver pieces. The British sovereign and half-sovereign are legal tender. There is a government savings bank in Belize, with branches in the principal towns; and in 1903 the British Bank of Honduras was established at Belize. The average of the revenue received in the five years ending in 1926 was £201,440—about £90,000 from customs duties. The expenditure, in which the cost of police and education are important items, averaged £230,864 during the same period. The public debt amounted in 1926 to £309,310. In 1927 the colony received a bequest under the will of Baron Bliss, who died at Belize, which provides an income of about £3,000 a year for public improvements and works of development.

**Constitution and Administration.**—From 1638 to 1786 the colonists were completely independent and their customs were codified as "Burnaby's laws," after the visit of Admiral Sir W. Burnaby in 1756, and recognized by the Crown. In 1786 a superintendent was appointed by the Crown, and although this office was vacant from 1790 to 1797, it was revived until 1862. An executive council was established in 1839, and a legislative assembly of three nominated and 18 elected members in 1853. British Honduras was declared a colony in 1862, with a lieutenant-governor, subject to the governor of Jamaica, as its chief magistrate. In 1870 the legislative assembly was abolished and a legislative council substituted, which now consists of five official and seven nominated unofficial members. In 1884 the lieutenant-governor was created governor and commander-in-chief and the colony rendered independent of Jamaica. The governor is assisted by an executive council of three official and three unofficial members. There are six administrative districts—Belize, Corosal, Orange Walk, the Cayo, Stann Creek, and Toledo. The capital of the last named is Punta Gorda; the others take the names of towns. English common law is valid throughout British Honduras, subject to modification by local enactments, and to the operation of the *Consolidated Laws of British Honduras*. Appeals may be carried before the privy council or the supreme court of Jamaica.

**Religion and Education.**—The churches represented are Roman Catholic, Anglican, Wesleyan, Baptist and Presbyterian; but none of them receives assistance from public funds. The bishopric of British Honduras is part of the West Indian province of the Church of England. Almost all schools are denominational. School fees are charged, and grants-in-aid are made to elementary schools. Most of these, since 1894, have been under the control of a board, on which the religious bodies managing the schools are represented.

## HISTORY

British settlement in Honduras, the scene of the ancient Maya civilization, begins with the coming of shipwrecked sailors or buccaneers in 1638. The first regular establishment followed in 1662, when settlers were attracted from Jamaica by the logwood and mahogany which soon became an important product of the bay. The woodcutters covered an area wider than Honduras, but for a century Spain did not admit their title, and English settlers tended to concentrate more and more on the Belize river, which gave an alternative name to the colony. In the 18th century they increased greatly in number, and African slaves were imported. The hostility of their Spanish rivals was keen and not unprovoked; and it was only after resisting formidable attacks that the English "baymen" were recognized by the treaty of Paris in 1763, and gained Spanish consent, at the price of destroying their fortifications, "not to be disturbed or molested, under any pretext whatever, in their said places of cutting and loading logwood." This agreement did not lead to friendly relations, and in 1779 the Spaniards made a grand attack which destroyed the settlement at Belize, the inhabitants being taken to Yucatan and Havana, where most of them died. In 1783 the survivors returned with new adventurers and resumed the cutting of timber; and by the treaties made in that year and in 1786 between England and Spain, they were recognized as having the right to cut both logwood and mahogany in the northern half of what later became British Honduras; but they were not to erect fortifications. In compensation, England gave up her claims to the Mosquito coast. When war broke out again the Spaniards prepared another great attack on Belize, but this was repulsed, and after 1798 the British were left in peace.

The successful resistance to Spain has been regarded as establishing British sovereignty over Honduras; but it is probably more correct to attribute the title to undisturbed possession than to conquest, as Spanish sovereignty appears to have been tacitly admitted in 1814, when the provisions of the earlier treaty were revived. With the break-up of Spanish power in Central America, any rights she might have were inherited by Mexico and Guatemala. The provisions of 1786 relating to this "settlement, for certain purposes, under the protection of his Majesty" were incorporated in a treaty with Mexico in 1826, and in the drafts of other treaties; and British authority over the greater area claimed in 1836 was later confirmed by the exception of Belize from the provision of the Clayton-Bulwer treaty (1850) which forbade the contracting nations to fortify points on the Central American mainland; and by the boundary settlement with Guatemala (1859). The country progressed peacefully under British rule, although the northern borders were occasionally attacked by rebel bands in the second half of the century. In 1849 an influx of Spaniards in flight from the Indians of Yucatan did much to populate the desert areas of the colony.

While the status of British Honduras was in dispute, government was by public meeting of the free inhabitants, who elected an unpaid magistracy of about seven, one being superintendent. The Crown granted a similar constitution in 1765. From this time gradual modifications were introduced, until in 1862 British Honduras became a colony with a lieutenant-governor under the governor of Jamaica. In 1871 it became a Crown colony and was separated from Jamaica in 1884. In 1890-92 a dispute, in which the minority of unofficial members resigned from the council, led to the reconstitution of that body, with a majority of unofficial members, the historical outcome of the colony's democratic origin.

**BRITISH INDUSTRIES FAIR.** The British Industries Fair owes its inception to the conditions brought about in 1914 by the sources of supply of many articles hitherto imported in large quantities by British firms being cut off as a result of the war.

To assist British manufacturers in undertaking the supply, a series of sample exhibitions, known as exchange meetings, were organized by the Board of Trade.

The logical sequel was the first British Industries Fair, held at the Royal Agricultural Hall in 1915, with a view to making the new British products known to the trade buyers. Some 600 exhibitors took part in it and the exhibits occupied an area of about 89,000 square feet. It was so successful that the Government was urged by the exhibitors to make it an annual event.

During the war years which followed the Fair was held under great difficulties, all suitable halls being needed for military purposes, and all trades capable of manufacturing munitions being necessarily debarred from participation. Nevertheless the fairs of 1916 and 1917, held at the Victoria and Albert Museum and the Imperial Institute, and of 1918 and 1919, held in large sheds at the London docks, were as successful as could be expected.

In 1920 the Fair had commenced to take its place in the commercial life of the country and, owing partly to the trade boom of that year and partly to the re-admission of the trades excluded during the war, it became necessary to move to the Crystal Palace, where 1,167 exhibitors took space.

The success of the Fair had resulted in the meantime in the organization of subsidiary sections at Glasgow and Birmingham, and, as exhibitors were classified on the basis of trades and no overlapping was permitted, the addition of these new sections raised important questions of policy. In 1920 a Board of Trade committee under the chairmanship of Sir Frank Warner, K.B.E., recommended that the Fair should be maintained on an annual basis with one section in London and one in Birmingham, and that the Glasgow section should be discontinued.

**London and Birmingham Sections.**—The Fair has continued to be held annually on the lines recommended by the committee, the London section being organized at the White City by the Department of Overseas Trade, and the Birmingham section at the Castle Bromwich aerodrome by the Birmingham Chamber of Commerce, under the auspices of the Birmingham Corporation, with the exception of the year 1925, when the London section of the fair was not held because of the British Empire Exhibition.

In 1925 the Government made a grant of £25,000 to defray the cost of publicity, with the result that the Fair of 1926 achieved a success which, coupled with a second grant for publicity, caused the Fair of 1927 to be, in its turn, yet more successful. As a result of the good business at the previous two years the space booked by exhibitors for the Fair of 1928 again increased very considerably and amounted in all to some 420,000 square feet.

The British Industries Fair, being an official organization for the increase of British trade, only permits the exhibition of British goods. It also restricts participation to manufacturing firms, or firms taking the whole output of a factory, so ensuring that, as any article can only be shown once and then only by its maker, trade buyers are able to inspect the exhibits and do their business in the most convenient manner. In both these points the British Industries Fair differs materially from the many fairs organized in Europe since the war. Another important point is the strict classification and clear division of the participating trades between the sections in London and Birmingham. As no overlapping is permitted the buyer knows that the whole of the exhibits in any particular trade will be found in either London or Birmingham. Practically all trades are eligible for participation, the machinery, hardware and allied trades forming the Birmingham schedule, while the remainder, mainly consisting of the "small goods" industries, such as silver and plate, cutlery, china, glass, musical instruments, leather goods, sports goods, wireless, and the textile, food and chemical industries are shown in London.

In addition to publicity in the press and by an elaborate system of correspondence direct with over 50,000 trade buyers in all parts of the world, the Government's commercial, diplomatic and consular services, and the trade commissioners and imperial trade correspondents within the British empire work successfully to make the Fair widely known in their respective districts. Active support is also given by British chambers of commerce both at home and abroad. An important feature of the propaganda is

the circulation abroad, a month before the opening of the Fair, of an advance edition of the catalogue.

With the exception of the grant for publicity, the fair is organized upon a self-supporting basis. The London section, being organized by the Department of Overseas Trade, is financed out of the vote for that department, the receipts from exhibitors being balanced against the expenditure. The Birmingham section is also self-supporting, the Birmingham Chamber of Commerce making themselves responsible for the finance of the enterprise. (C. TA.)

**BRITISH ISLES:** see GREAT BRITAIN; IRELAND; SCOTLAND; WALES; etc.

**BRITISH LEGION.** The British Legion was established in 1921, under the late Field-Marshal Earl Haig, its first president, for the purpose of uniting in one national organization the various existing associations of ex-service men. These were the Comrades of the Great War, the National Association of Discharged Sailors and Soldiers, the National Federation of Discharged and Demobilized Sailors and Soldiers, and the Officers' Association. In April 1925 the Legion was incorporated by royal charter.

The principles and policy of the Legion are non-political and non-sectarian, and its membership is open to all British or naturalized British men and women who have served with the forces of the Crown, including men and women of the Red Cross and similar organizations.

The activities of the Legion are administered through various departments dealing with legal and financial aid, appointments and employment, assistance of various kinds to families, including educational assistance and the after-care of children, as well as a business branch for setting up ex-service men in business. A Legion industrial village settlement has been established at Preston Hall, near Aylesford, Kent, where tubercular cases are received. It comprises a sanatorium with park grounds and cottages covering in all 450ac., where the patients, who in some cases have their families with them, when fit to work, are taught to pursue a great variety of suitable occupations, including carpentry, printing, fibre and leather case manufacture, etc. With the aid of the National (Prince of Wales') Relief Fund, as well as through private generosity, the Legion has also acquired a factory fully equipped for the manufacture of handwoven Welsh tweeds by disabled ex-service men, and in the Ex-service Industries, Ltd., at Warminster, has financed another similar undertaking for the manufacture of furniture.

Another of the Legion's practical activities is the poppy factory, where over 200 disabled men are employed all the year round making the "Flanders" poppies and wreaths in anticipation of the demands for Remembrance Day (Nov. 11). The sale of these poppies throughout the country on that day has been recognized as constituting a special appeal in aid of the funds of the Legion, and the total contribution from all sources made on "Poppy Day" is now the main source of income for its work, and in 1927 realized the sum of £513,000. The co-ordination of this and other appeals and funds, such as the United Services, the British Red Cross and others, for the relief of distress among ex-service men and their families, is made through the national executive council. Further a representative of the Legion serves on every committee in the country that has to do with pensions.

The organization of the Legion, whose headquarters are in London, is based on the establishment of over 2,600 branches throughout the country, as well as a number of branches abroad, including Geneva, Lima, Mexico city, etc. The branches are grouped into administrative areas, each with its own elected council, the national executive council being also elected annually at the conference of branch delegates. Through its membership of the British Empire Services League and association with the *Fédération Interalliée des Anciens Combattants*, the British Legion also maintains its contact, and serves as a connecting link, with the other ex-service organizations of the British Dominions and allied nations in the World War.

**BRITISH MUSIC SOCIETY.** This is a body which was formed in 1918, on the initiation of Dr. Eaglefield Hull and under the presidency of Lord Howard de Walden, to further the interests of British music and of music in general in Great Britain. The

society aims at stimulating the musical life of the nation, alike by developing and co-ordinating the work of existing organizations and by its own activities carried on through the agency of its various provincial centres and local branches throughout the country. At the same time, in virtue of its relations with the International Society for Contemporary Music, of which it constitutes the British section, the society is in close touch with Continental music.

**BRITISH NATIONAL OPERA CO., THE.** came into existence in 1922 when it was formed on so-called "common-wealth," or profit sharing, lines by some of the leading artists who had found their occupation gone on the cessation of Sir Thomas Beecham's managerial activities, a company of notable strength and efficiency resulting. The company's activities are confined mainly to the provinces, but it has also given seasons in London. Operas of all schools, including several modern British works, are comprised in its repertory.

**BRITISH SOUTH AFRICA COMPANY, THE.** This company owes its existence mainly to the creative genius of the late Mr. Cecil Rhodes, who in the early 'eighties of the last century saw that, unless Great Britain bestirred herself, large tracts of valuable country ruled by savage native chiefs in the interior of Africa would pass into the hand of the continental Powers then engaged in a scramble for new colonies. The reports of explorers had convinced him that the high lands north and south of the Zambesi river not only provided favourable fields for colonization and agricultural development but contained the promise of great mineral wealth. Upon these tracts the eyes of Transvaal Boers and Germans were already fixed, while Portugal, after centuries of apathy, was beginning to assert historical claims to their ownership.

Rhodes first tackled the problem of acquiring a foothold in the Matabele and Mashona country, and with that object secured the despatch to King Lobengula of a diplomatic mission to establish an understanding between him and the Government of Queen Victoria. This, being successful, was followed in 1888 by a more special mission which succeeded in obtaining from Lobengula a concession of mineral rights over the whole of what is now Southern Rhodesia. Other financial groups which claimed to have secured local mineral concessions and trading rights were persuaded to throw in their lot with Rhodes, and he was thus enabled to approach the British Government with a petition for a charter authorizing him to undertake the development and administration of all that part of the interior of south Central Africa not definitely appropriated by Belgians, Germans, and Portuguese.

**Royal Charter, 1889.**—The Royal charter was granted on Oct. 29, 1889. By adroit handling Lobengula was next induced to permit the entry of an expedition composed of settlers and police. This arrived on Sept. 12, 1890, at the site of the modern town of Salisbury, which thereafter became the headquarters of the Chartered Company's government and the focus of its activities. Simultaneously Rhodes despatched expeditions to various regions north of the Zambesi and obtained land and mineral concessions over Barotseland, and, in concert with the late Sir Harry Johnston, over a great part of the territory lying between Lakes Nyasa, Tanganyika, Mweru, and Bangweulu, which districts were afterwards administered by the British South Africa Company under the names of north-western and north-eastern Rhodesia respectively.

During the years immediately following the occupation of Mashonaland the European settlers, as was almost inevitable, had to encounter opposition from the savage Matabele on their borders, who were loth to abandon their traditional practice of raiding and plundering the weaker tribes whom the company had taken under their protection. To this cause was due the Matabele War of 1893, which resulted in the defeat of Lobengula's army by a small body of the settlers headed by the Company's administrator, Dr. L. S. Jameson, and the flight, followed by the death, of the chief himself. The Crown then consented to extend the administration of the Chartered Company over Matabeleland and gave effect to this by an Order in Council dated July 1894.

For some years the fortunes of the new settlements fluctuated.

A determined rebellion broke out in Matabeleland in March 1896 and was immediately followed by a rising of most of the tribes in Mashonaland. In both provinces a large number of isolated settlers were trapped and murdered in cold blood. In Matabeleland, after some months of indecisive fighting, Rhodes, with great courage, went almost alone into the rebel stronghold and arranged terms of peace with the leaders. In Mashonaland the hostilities were more protracted, but were finally brought to an end by the surrender of the rebels in Oct. 1897. Thenceforward the record of the country is one of unbroken progress. A legislative council was instituted and the principle of popular representation was introduced, agricultural industries established, and mining for gold and other minerals actively carried on.

Rhodes successfully financed the construction of a trunk line of railway connecting the Cape system with the north, and Mashonaland with the more convenient port of Beira in Portuguese East Africa. The Chartered Company was thus the parent of the Rhodesia railway system, which now extends from Vryburg in Bechuanaland to the borders of the Belgian Congo, and from Bulawayo to the east coast of Africa—some 2,500 miles of railway line in all.

The whole expense of the Chartered Company's operations, including the cost of quelling the various native disturbances, was borne by its shareholders without assistance from the British taxpayers.

**Southern Rhodesia and Self-Government.**—In 1923 the settlers of Southern Rhodesia felt themselves strong enough to demand self-government. An alternative proposal that the territory should become incorporated in the Union of South Africa was submitted to a referendum and rejected by a large majority. Southern Rhodesia was granted self-government in 1923, and in the following year the territories lying north of the Zambesi were given the status of a protectorate of the Crown. In both cases the company was relieved of the administrative obligations which it had faithfully carried out for 33 years. During that period, besides developing the agricultural and mineral resources of the countries embraced within its charter, the company succeeded in completely eradicating the slave trade, which from time immemorial had been carried on by many of the native chiefs encouraged by Arabs from Zanzibar and other parts of East Africa; it had strangled the traffic in alcoholic liquor, prohibiting its sale to the natives under the most rigid penalties; it had established a system of native education and had set aside reserves whereon the natives could continue to live under tribal conditions, and had given facilities to Christian missionaries of all creeds to carry on their civilizing work in every part of the territory.

At the termination of the Chartered Company's administration the Imperial Government arranged to refund to it a portion of the heavy expenditure which it had incurred in discharging the obligations of the charter, and the Southern Rhodesia Government assumed its share of this expenditure as a public debt. The Chartered Company was also allowed to retain such areas of land as it had appropriated for agricultural and ranching purposes and the benefit of extensive land concessions in Northern Rhodesia and Nyasaland. It retains also the mineral rights originally acquired from native chiefs, which cover the whole of Rhodesia north and south. As holding the great majority of the shares in the companies operating the various sections of the railways it is virtually the proprietor of the whole system.

During the period of administration the financial burdens imposed upon the company were too heavy to permit of any return to the shareholders, but within a year of being relieved of these burdens the directors were able to refund 5s. on every £1 share, and since that date dividends have also been regularly paid. The capital of the company, originally £1,000,000, has by successive increases been raised to £6,750,000. The president of the company is Sir Henry Birchenough, Bt., K.C.M.G., who is also chairman of the companies controlling the Rhodesia railway system.

Hone, *Southern Rhodesia* (1909); Basil Williams, *Cecil Rhodes* (1921); Ian Colvin, *Life of Jameson* (1922); H. Marshall Hole, *The Making of Rhodesia* (1926).

**BRITISH THERMAL UNIT**, the amount of heat required to raise one pound of water through one degree Fahrenheit, denoted by the abbreviation B.T.U. (See UNITS, PHYSICAL.)

**BRITOMARTIS**, "sweet maiden," an old Cretan goddess, later identified with Artemis, whose favourite companion she is said to have been. Being pursued by Minos, king of Crete, who was enamoured of her, she sprang from a rock into the sea, but was saved from drowning by falling into some fishermen's nets. Made a goddess by Artemis as *Dictynna* (*δίκτυον*, net), she was the patroness of hunters, fishermen and sailors, and also a goddess of birth and health. The centre of her worship was Cydonia, whence it extended to Sparta and Aegina (where she was known as Aphaea) and the islands of the Mediterranean. By some she is considered to have been a moon-goddess, her flight from Minos and her leap into the sea signifying the revolution and disappearance of the moon.

**BRITON-FERRY**, urban district, Glamorganshire, Wales, east bank, estuary of Neath river in Swansea bay. Population (1921) 9,165. The name La Brittone was given by the Norman settlers of the 12th century to its ferry across the estuary of the Neath, but the Welsh name of the town, at least from the 16th century, has been Llansawel. The district was formerly celebrated for its scenery, but this has been marred by industrial developments. The Vale of Neath canal built in 1797 has its terminus at Briton-Ferry, which became the port for the rapidly developing Neath valley. The construction in 1861 of a large dock by the G.W.R. and the opening up about the same time of the mining districts of Glyncoerrwg and Maesteg by means of the South Wales Mineral railway made the town a leading exporting centre of the coal field. The development of metallurgical industries in the south Wales coast towns brought further prosperity to Briton-Ferry. Steel, tin-plate and galvanized goods are manufactured on a large scale. Trade depression since 1918 has severely affected all aspects of the town's trade. The town has stations on the G.W.R. main line and on the old Rhondda and Swansea Bay line (now G.W.R.).

**BRITTANY** or **BRITANNY**, an ancient province and duchy of France (Fr. *Bretagne*), known as Armorica (*q.v.*) until the influx of Celts from Britain. It consists of the northwest peninsula, nearly corresponding to the departments of Finistère, Côtes-du-Nord, Morbihan, Ille-et-Vilaine and Lower Loire. It is popularly divided into Upper or Western, and Lower or Eastern Brittany. Its greatest length between the English channel and the Atlantic ocean is 250 km. (about 155 English miles), and its superficial extent is 30,000 sq. km. (about 18,630 English sq. m.). It comprises two distinct zones, a maritime zone and an inland zone. In the centre there are two plateaus, partly covered with *landes*, unproductive moorland; the southern plateau is continued by the Montagnes Noires, and the northern is dominated by the Monts d'Arrée. The waterways of Brittany are for the most part of little value owing to their torrent-like character. The only river basin of any importance is that of the Vilaine, which flows through Rennes. The coast is very much indented, especially along the English channel, and is rocky and lined with reefs and islets. The mouths of the rivers form deep estuaries. In the 19th century the development of new means of communications drew Brittany from its isolation, and agriculture developed in a remarkable manner. Many of the *landes* were cleared and converted into excellent pasturage, and on the coast market-gardening made great progress. In the fertile districts cereals are cultivated. Industrial pursuits, except in a few seaport towns, which are rather French than Breton, have hitherto received but little attention. The Celtic language is still spoken in Lower Brittany. Four dialects are clearly marked (see BRETON LANGUAGE). (X.)

## HISTORY

The earliest inhabitants of whom we have a record were Celtic tribes, probably mixed with remnants of the earlier race whose monuments are the cromlechs and stone circles. The Roman name of the country—Armorica—is Celtic. Caesar invaded it in 56 B.C., and the Bretons took part in the unsuccessful rising against him in 52–51 B.C. Roman rule then lasted till the 5th century A.D.

After the withdrawal of the Romans, there came, in the 5th and 6th centuries, a considerable immigration of the Celts of Britain, taking refuge among their continental kinsmen from the Saxon invasion. Till then, the rural population had still been mostly pagan, but now for 300 years Breton history and tradition are largely occupied with records and legends of the Celtic missionaries from Britain and Ireland, who gradually converted the whole country and gave their names to towns and villages (such as St. Malo, St. Brieuc, St. Tugdual, and St. Pol). Until a national hero, Nominoë, united its people against the Norse raiders of the 9th century, Brittany was divided into a number of petty lordships. Nominoë accepted the suzerainty of the French king, Louis the Pious, but revolted in 846 against Charles the Bald, and restored Breton independence.

The raids of the Norsemen continued into the 10th century. In its second half, Conan of Rennes became paramount in Brittany. His son Geoffrey took the title of duke. Breton adventurers fought under William of Normandy at Hastings, but the Breton dukes successfully opposed his attempts to add their country to his conquests. The line of Conan ended in the 12th century. Duke Conan IV., hard pressed by rebellious nobles, sought the help of Henry II. of England and gave his daughter Constance in marriage to Henry's son, Geoffrey Plantagenet, who succeeded to the dukedom. His heir, Arthur, was murdered by John Lackland, but Arthur's sister married a French noble, Pierre de Dreux, who became duke of Brittany in 1212. A line of French dukes ruled at Rennes until, on the death of the childless Jean III. in 1341, civil war began between the partisans of two indirect heirs, Jean de Montfort and Charles de Blois. The defeat and death of Charles at Auray (1364) secured the Dukedom for the house of Montfort. The Breton hero, Bertrand Duguesclin, won his first honours in this "war of succession." Later, as constable of France, he fought against the English invaders. Tales of his prowess in battle and tourney are traditional in Brittany.

Brittany's independence practically ended in 1491, when Duke Francis I. died without a son, and his daughter, the duchess Anne, married Charles VIII. of France. Her daughter, Claude, became the queen of Francis I., under whom the treaty of 1532 was concluded, annexing Brittany to France, with guarantees for its local liberties. Until the revolution this provincial autonomy survived, local patriotism opposing the attempts at centralization made by Bourbon absolutism. The mass of the people had remained unaffected by the reformation. During the war of the league there were conflicts with the Huguenots. The peace of 1593 was followed by local troubles arising from the duke de Mercœur's attempt to make himself duke of Brittany. The province then had a long period of peace interrupted only by an unsuccessful rising in 1675 against new taxation—the "revolt of the stamped paper." Many Bretons distinguished themselves in seafaring enterprise—men like Cartier, the maker of French Canada, and the naval heroes, Surcouf and Duguay Trouin.

The revolution at its outset found support in Brittany, but the abolition of the monarchy and the new church laws led to risings, which began in the winter of 1792. The last shots were fired in 1799. The disembarkation of an *émigré* force at Quiberon in 1795 ended in tragic disaster, 1,000 disarmed royalists being massacred by the republicans. The last stage of the resistance was the guerilla warfare of the "Chouans."

Brittany was long after royalist, republicanism being associated with memories of these tragic years and of the anti-religious campaign of the Jacobins. Later there has been a notable movement towards conservative republicanism. In the World War Breton regiments were among the best soldiers of France, and the Breton Admiral Ronarch, in the critical autumn battles of 1914, held a position on the Yser hardly less vital than Ypres itself.

**BRITTLE STARS**, the popular name for star-fish (*q.v.*) of the class Ophiuroidea (see ECHINODERMA). The name refers to the habit of these animals of breaking off their arms (autotomy, *q.v.*) when alarmed.

**BRITTON, JOHN** (1771-1857), English antiquary, was born on July 7, 1771, at Kington-St.-Michael, near Chippenham, Wilts. Along with his friend Edward Weldeke Brayley, Britton produced *The Beauties of Wiltshire*, 2 vols. (1801; a third added in 1825), the first of the series *The Beauties of England and Wales*, nine volumes of which Britton and his friend wrote. Britton created the taste for popular books on topography. His numerous works include: *Architectural Antiquities of Great Britain*, 9 vols. (1805-1814); and *Cathedral Antiquities of England*, 14 vols. (1814-1835). He died in London on Jan. 1, 1857. His *Autobiography*, which brings the account of his life down to about 1825, was published in 1850. The best notice of Britton is by Digby Wyatt, *Papers of the Royal Institute of British Architects* (1856-57).

**BRITTON, NATHANIEL LORD** (1859- ), American botanist, was born at New Dorp, Staten Island, New York, on Jan. 15, 1859. He graduated in 1879 at Columbia university from which in 1881 he received the degree of doctor of philosophy. After serving as instructor in geology in 1879-87 and as instructor and adjunct professor of botany in 1886-91, he was made professor of botany in Columbia university. He occupied this chair until 1896 when he became director-in-chief of the New York Botanical Garden, created as the result of his efforts and which under his guidance became one of the leading institutions for the advancement of botanical science. He early became a keen student of plants and rose to front rank among American systematic botanists, specializing in the North American flora, notably in the Crassulaceae, Cactaceae and Cyperaceae, and in the flora of the West Indies, Bolivia and Paraguay. Besides writing numerous botanical papers and editing the *Bulletin of the Torrey Botanical Club*, 1888-97, he was the author of important botanical works among which are: *Illustrated Flora of the Northern United States and Canada*, with Addison Brown (1896-98, 2nd ed., 1913); *Flora of Bermuda* (1918); *The Bahama Flora*, with C. F. Millspaugh (1920); *Monograph of the Cactus Family*, with J. N. Rose (1919-20), and various portions of the monumental *North American Flora* (1910- ).

**BRITTON**, the title of the first great treatise of the law of England in the French tongue, which purports to have been written by command of King Edward I. The author is probably either John le Breton, a justice for the county of Norfolk, or a royal clerk of the same name. The probable date of the book is 1291-92. It was based upon the treatise of Henry de Bracton (*q.v.*), which it brought up to date. The work is entitled in an early ms. of the 14th century, which was once in the possession of Selden, and is now in the Cambridge university library, *Summa de legibus Anglie que vocatur Bretonne*; and it is described as "a book called Bretonne" in the will of Andrew Horn, the learned chamberlain of the City of London, who bequeathed it to the chamber of the Guildhall in 1329, together with another book called *Miroir des Justices*.

*Britton* was first printed in London by Robert Redman, without a date, probably about the year 1530. Another edition of it was

printed in 1640, corrected by E. Wingate. A third edition of it, with an English translation, was published at the University Press, Oxford, 1865, by F. M. Nichol. An English translation of the work without the Latin text had been previously published by R. Kelham in 1762.

**BRIVE** or **BRIVES-LA-GAILLARDE**, a town of France, capital of an arrondissement, department of Corrèze, 62m. S.S.E. of Limoges on the main line of the Orleans railway from Paris to Montauban. Pop. (1926) 20,299. It lies on the left bank of the Corrèze in a fertile plain where important roads and railways meet, and where the high Plateau Central grades down to the south-western plain. Rock caves give local evidence of man in early prehistoric times and great stone monuments show later occupation. Known to the Romans as Briva Curretiae (bridge of the Corrèze), in the middle ages it was the capital of lower Limousin, and St. Anthony of Padua founded a Franciscan monastery here in 1226. The *enceinte* which formerly surrounded the town has been replaced by boulevards. Outside the boulevards lie the modern quarters. A fine bridge leads over the Corrèze to suburbs on its right bank. The church of St. Martin in the heart of the old town is a building of the 12th century in the Romanesque style of Limousin, with three narrow naves of almost equal height. The ecclesiastical seminary occupies a graceful mansion of the 16th century, with movable façade, staircase and fireplaces. Brive's position makes it a market of importance with large trade in the early vegetables, nuts and fruit of the Corrèze valley, and in live stock, liqueurs and truffles. Table delicacies, paper, wooden shoes, hats, candles, and earthenware are made, and there are slate and millstone workings and dye works. Brive is the seat of a sub-prefect and has a tribunal of first instance, a tribunal of commerce, and a school of industry.

**BRIXEN** (town, North Italy): see BRESSANONE.

**BRIXHAM**, seaport and urban district, Devonshire, England, 33m. S. of Exeter, on a branch of the G.W. railway. Pop. (1931) 8,147. The town is irregularly built on the cliffs to the south of Torbay, and its harbour is sheltered by a breakwater. Early in the 19th century it had important fortified barracks on Berry Head. It is the headquarters of the Devonshire sea-fisheries, having also a large coasting trade and coastguard and life boat stations. Shipbuilding and the manufacture of ropes, paint and oils are carried on. Brixham is in favour as a seaside resort. St. Mary's, the ancient parish church, has an elaborate 14th century font and some monuments of interest. At the British Seamen's Orphans' Home boys are fed, clothed and trained as apprentices for the merchant service. A statue commemorates the landing, in 1688, of William of Orange.

**Brixham Cave**, called also Windmill Hill Cavern, is a well-known ossiferous cave situated near Brixham, with a fauna closely resembling that of Kent's Hole. The implements are of a roughly-chipped type. The formation of the cave was carried on simultaneously with the excavation of the valley; the small streams, flowing down the upper ramifications of the valley, entered the western opening of the cave, and traversing the fissures in the limestones, escaped by the lower openings in the chief valley.

**BRIXTON**, a district with railway station (S.R.) in the south of London, England, included in the metropolitan borough of Lambeth (*q.v.*). Pop. of parl. district (1931) 74,536.

**BRIZEUX, JULIEN AUGUSTE PÉLAGE** (1803-1858), French poet, was born at Lorient (Morbihan). In 1827 he produced at the Théâtre Français a one-act verse comedy, *Racine*, in collaboration with Philippe Busoni. Brizeux's second visit to Italy in 1834 resulted in the publication of a complete translation of the *Divina Commedia* in *terza rima* (1841). With *Primel el Nola* (1852) he included poems written under Italian influence, entitled *Les Ternaires* (1841), but in the rustic idyll of *Marie* (1836) he turned to Breton country life; in *Les Bretons* (1845) he found his inspiration in the folk-lore and legends of his native province, and in *Telen-Aroor* (1844) he used the Breton dialect. His *Histoires Poétiques* (1855) was crowned by the French Academy. His work is small in bulk but is characterized by simplicity and sincerity.

See C. Lecigne, *Brizeux, sa vie et ses œuvres* (1898).

**BRIZO**, an ancient goddess, long worshipped in Delos. She delivered oracles in dreams to those who consulted her about fishery and seafaring. The women of Delos offered her presents consisting of little boats filled with all kinds of eatables (except fish) in order to obtain her protection for those engaged on the sea.

**BRNO** (Ger. Brünn), the capital of Moravia, Czechoslovakia, is situated at the confluence of the Svratka and the Svitava, between two hills, one of which, the Spielberg (945ft.), is crowned by a fortress now used as a barracks but which formerly was an Austrian political prison. In this capacity it was rendered famous by the narrative of Silvio Pellico who was confined there from 1822 to 1830. On the lower hill lies the cathedral of St. Peter dominating the old town, which, though small and traversed by narrow, crooked streets, contains most of the important civic and ecclesiastic buildings, many of them, e.g. the Rathaus (1511), and the 15th century church of St. Jacob, rich in interesting antiquities. Around the old town fine gardens and well-built streets have replaced the fortifications and connect old and new; 9th century Brno gives place here to the busy manufacturing suburbs of the 19th and 20th centuries. The town is the headquarters of the Czechoslovak cloth and woollen manufactures which, as well as the manufacture of machinery, are based upon the neighbouring Rosice-Oslavany coalfield. Brewing, distilling, milling, sugar-refining, etc., reflect the fertility of the territory in which Brno lies. It is now the seat of the Supreme Court and the establishment of the Masarykova University (1918) revives the spirit of its mediaeval predecessor and enables Brno once more to make its full contribution to civilization. Pop. (1921) 221,758, of whom 70% are Czechs and 25% German.

**BROACH** or **BHARUCH**, an ancient city and modern district of British India, in the northern division of Bombay. The city is on the right bank of the Nerbudda, about 30m. from the sea, and 203m. N. of Bombay. The area, including suburbs, occupies 2½ square miles. Pop. (1921) 42,648. The sea-borne trade is confined to a few coasting vessels. There is a considerable cotton industry; flour milling and handicrafts are also carried on. The fort containing the civil courts, the gaol, church, municipal offices, etc., stands on a hill above the river. Broach is the Barakacheva of the Chinese traveller Hsüan Tsang and the Barygaza of Ptolemy and Arrian. Upon the conquest of Gujarat by the Mohammedans, and the formation of the State of that name, Broach formed part of the new kingdom. On its overthrow by Akbar in 1572, it was annexed to the Mogul empire and governed by a nawab. The Mahrattas became its masters in 1685, from which period it was held in subordination to the Peshwa until 1772, when it was captured by a force under Gen. Wedderburn, who was killed in the assault. In 1783 it was ceded by the British to Sindhia in acknowledgment of certain services, but was stormed in 1803 by a detachment commanded by Col. Woodington, and finally ceded to the East India Company by Sindhia.

The District of Broach contains an area of 1,468 square miles. Consisting chiefly of the alluvial plain at the mouth of the river Nerbudda, the land is rich and highly cultivated, and though it is without forests it is not wanting in trees. The district is well supplied with rivers, having in addition to the Nerbudda the Mahi in the north and the Kim in the south. Pop. (1921) 307,745, comprises several distinct races or castes, who, while speaking a common dialect, Gujarati, inhabit separate villages. The principal crops are cotton, millet and pulse. There is extensive dealing in cotton, the dealers being organized in a guild. Besides the cotton mills in Broach city there are several factories for ginning and pressing cotton, some of them on a very large scale. The district is traversed by the Bombay and Baroda railway, which crosses the Nerbudda opposite Broach city on an iron-girder bridge of 67 spans.

**BROACH**, a word used for any one of many forms of pointed instruments, such as bodkins, wooden needles used in tapestry, roasting spits and even the tools (also called "rimers" or "reamers") employed for enlarging or smoothing holes. Hence comes the expression "to broach" for "to tap" a cask. In architecture, the term is used specifically to designate a triangular

surface inserted in the corners of a square or cube to make the upper face an octagon, especially at the junction of a square tower and an octagonal spire, in which case, the slope of the broached surface is usually less than that of the spire sides. The word also is used for any means of adjusting a polygonal spire to a square base and even, loosely, as synonymous with squinch (*q.v.*).

**BROADBENT, SIR WILLIAM HENRY**, 1ST BARONET, (cr. 1893) (1835-1907), English physician, was born at Lindley, near Huddersfield, on Jan. 23, 1835, the son of a woollen manufacturer. He studied at Owens College, Manchester, and Manchester Royal School of Medicine, and then in Paris under Trousseau, Ricord, Reyer and others. He became resident medical officer of St. Mary's Hospital, London, in 1859, and in 1869, pathologist and lecturer on physiology and zoology in the medical school there. From 1860-79 he was physician at the London Fever Hospital, but he retained his association with St. Mary's Hospital in various capacities until 1896, and after that date remained an honorary consulting physician. He attended the Duke of Clarence (1892) during his fatal illness, and in that year became physician in ordinary to the Prince of Wales (Edward VII.), and in 1896 physician extraordinary to Queen Victoria. He was physician in ordinary to King Edward VII. and the Prince of Wales (George V.).

Broadbent did much important work in connection with paralysis and his name is associated with "Broadbent's hypothesis" explaining its unequal distribution in various parts of the body in the ordinary form of hemiplegia. His memoir "On the Cerebral Mechanism of Speech and Thought" (*Trans. Roy. Med. Chir. Soc.*, 1872) and later papers, are important contributions to the literature on the brain. Many of his papers on clinical questions were collected by his son, Dr. Walter Broadbent (1908).

Broadbent held many offices in connection with medical societies, and took an active part in public health work, particularly in promoting (1899) the National Association for the Prevention of Consumption, and in the organization (1901) of the British Congress on Tuberculosis, and received many academic honours; he was elected F.R.S. in 1897. He died in London on July 10, 1907.

**BROAD-BOTTOM MINISTRY**, in English political history a term applied to the wide Coalition Ministry formed after the fall of Carteret in 1744, between the existing Ministry under the Pelhams and the Opposition led by Lord Chesterfield. The name is said to have been first coined at the formation of the Ministry of 1742; but it was universally applied to the Ministry of 1744, which has since been always known to history as the Broad-Bottom Administration. Chesterfield was its real leader, and the nickname receives an extra significance from the fact that he had recently published a series of letters in the *Constitutional Journal* under the pseudonym of "Jeffrey Broadbottom." The opposition of the king at first excluded Pitt; but early in 1746 he was admitted to a subordinate post. With some changes the Ministry survived until the death of Henry Pelham in 1754.

**BROADCASTING**. Broadcasting, as distinct from wireless communication, may be said to have come into being about 1920. It may be defined as the systematic diffusion, by radio telephony, of music, lectures, drama, humour, news and information bulletins, speeches and ceremonies, pictures and other matter susceptible of appreciation by a scattered audience, individually or in groups, with appropriate receiving apparatus. The expression "appropriate apparatus" must be taken as applying not only to technical and artistic suitability but to qualities such as cheapness and ease of management.

#### GENERAL EUROPEAN SYSTEMS

Whether broadcasting is conducted as a public service as in Great Britain and several other countries, or also as a means of attracting commercial goodwill as in the United States of America and elsewhere, the results tend to become unexpectedly similar, and the material that is acceptable from the point of view of commercial goodwill differs only by fine shades from what is suitable from the point of view of the non-commercial broad-

FIG. 1.—SCHEMATIC DIAGRAM OF A BROADCASTING SYSTEM

caster animated by a sense of his public mission. Even the successful acquisition of commercial goodwill depends more and more upon the interested party assuming the rôle of public benefactor, and his broadcasts are somewhat in the nature of a *leitourgia* of ancient Athens.

From 1919 onward, amateur wireless experimenters, who were numerous even before the war, worked more and more in telephony in preference to Morse telegraphy, and in England and several other European countries broadcasting began spontaneously with transmissions of gramophone records and amateur performances. At the same time the radio industry began to foresee and prepare for a future of evidently great but unknown possibilities. Experimental work was undertaken for the improvement of microphones, and for the development of listening apparatus which could be operated with a minimum of technical knowledge. Arrangements began to be made (in some cases under considerable difficulties due to the claims of vested interests) for the regular transmission of programmes. Thus, an innovation, comparable in cultural importance to the introduction of printing, was launched tentatively upon a responsive Europe, before either the financial organization of broadcasting services or their relations with the theatre, the musical profession, the press, the wireless industry, or existing wireless services had been properly settled, and while the conditions for good broadcasting were unexplored. The nations of Europe pushed on with the organization of regular broadcasting services so fast that by the end of 1925 over 90, and by the end of 1927 practically 200 stations, were in operation.

The first result of this rapid growth was an imminent danger of chaos, and it was the first task of the Union Internationale de Radiophonie (headquarters Geneva), formed in April 1925 at a conference of European broadcasters held at the headquarters of the British Broadcasting Company, to remedy this situation. The task was one of extreme difficulty, as the conflicts to be adjusted were those of perfectly legitimate interests, and the character of the union as an unofficial body left its decisions open to ratification or reversal by the several national Governments, but a tentative pan-European scheme was devised and largely put into operation by Nov. 1926, and its working kept under constant observation. Other domains of the union's activity concern copyright law, exchange of experience and consideration of common policy *vis-à-vis* performers, authors, press, concert and theatrical interests, etc., international transmissions of programmes for terminal broadcast by telephone lines, and generally the promotion of international smooth working and good feeling.

### PROGRAMMES

As a broad classification, programme elements may be divided into music and speech. For broadcasting purposes, music, whether concerted or solo, instrumental or vocal, is best classified according to character and appeal; viz., as serious, popular and dance music. The proportions of each that are included in any day's or week's programmes vary according to the conceptions of the programme authorities, their resources in artists from day to day and the demands of the public.

Broadcast speech includes (a) informative and practical utility matter such as news, market prices, weather reports, time signals,

agricultural bulletins and notices of various sorts (*e.g.*, appeals for charity, police notices, club or association bulletins and notifications of dangerous illness to relatives whose address is unknown); (b) "talks," *i.e.*, short lectures or series of lectures on all sorts of subjects, critiques of literature, drama, music and films, courses of education addressed to schools in school hours or to adults, and debates; (c) important public speeches, ceremonies, matches and events taken by a microphone on the spot; (d) religious services, either specially arranged for broadcasting, or taken by a microphone from church or chapel; (e) radio drama, a form of dramatic presentation in which all effects other than vocal have to be conveyed to the ear or suggested to the imagination, and which calls, therefore, for a special technique in playwriting and acting; (f) short programmes of entertainment and instruction for children; (g) humorous entertainment; (h) advertisement; and (i) political or other propaganda. To these must be added the possibilities of television. Further, there are miscellaneous special broadcasts, such as words of command for physical exercises performed by listeners at home, or messages from an explorer in the heart of a distant country.

**The Principles of Selection.**—The mere catalogue of these activities is enough to indicate the immense social importance of broadcasting. So far, it is only under the headings (e) and (f) above that radio has created expression-forms peculiar to itself, and in all other respects programme-building is creative only in the sense that the programme-builders can build combinations of suitable music and speech round one or another central idea. More generally, too, they can create (or evoke and nurse) a mass-disposition towards certain aims and preferences. Practically, then, their power is no more and no less than the power of selection, which is qualified by the need of balancing the character of successive or simultaneous programmes so as to give a fair measure to all reasonable tastes or to ensure a fair field to speakers of all points of view. Here and there constitutional limitations or police instructions limit the scope. Established interests such as the press, the theatre and the musical industry, have in many cases safeguarded their special fields in various ways; and technical requirements also operate to a certain, though rapidly diminishing, extent as a check.

It is coming to be recognized also that, from the social standpoint, it is vitally important that programme-builders should be governed by ideals and standards defined by themselves as a rule of conduct. This question affects every aspect of a programme service. A well-developed national broadcast system has the ear of far more people than any two or three newspapers, and this, coupled with the fact that the microphone is the most intimate and insinuating of all known vehicles of general communication, makes it perhaps more potent for good or evil than any other social influence.

**Alternative Programmes.**—As no one is entitled to dictate that the public shall hear only what he himself would care to hear, as the available programme material exceeds the capacity for dealing with it, and as the listener's temporary mood must be catered for no less than his settled tastes, programme policy must seek to provide (so far as the technical and financial limitations of each case permit) for more than one programme to be available

at any given time for any given listener. The American system of unrestricted competition was expected to provide this very freedom of choice, but in practice the alternatives simultaneously transmitted are apt to be simultaneously received also. Experience tends to show that the number of available programmes is simply the number of definitely and locally separable wave-lengths; it is a function, therefore, of the selectivity of the average receiving set, the power and position of the stations. In Europe, in the present (1928) state of knowledge and of cost of popular apparatus, an effective service of alternative programmes depends on (a) the skilful use of some simultaneous broadcast system and (b) high-power transmission, which gives great range to the individual station and therefore, over a given region, fewer stations and more separation between wave-lengths. There is, however, a limit to this simplification by reduction of number and increase of power, in that for transmissions on the medium wave band (200-600m., or 500-1,500kc.) attenuation becomes excessive, and "fading" also intervenes, beyond the range of 80-100 miles. Hence, in considering any particular country of irregular shape, the proper location of its stations is a difficult matter, turning upon the density distribution of the population as much as upon purely geographical considerations, and in particular cases the low-powered station for purely local service may continue to be the best mode of giving service. In general, it is possible to separate studios (or other places of performance) from transmitters in such a way that the artistic resources of a country can be tapped wherever they exist, while the actual emission takes place from points chosen solely for geographical and demographical reasons. In other cases, again, an area may best be covered by combining a high-power station with two, three or more low-power, on the same or on different frequencies.

#### THE PROCESS OF BROADCASTING

The actual process of broadcasting, though complicated in detail by the variety of the items broadcast and by their volume (which amounts for instance to about 66,000 transmission hours annually for the British broadcasting system), is simple enough in outline. Most of the performances take place in a studio, which is carefully arranged so as to give, for the necessarily small room, an acoustical condition that is pleasing to a musical judgment as applied to the receiver. This requires a certain amount of echo elimination, by drapery and otherwise (in British practice a fixed amount of natural echo with partial superposition of a controllable "artificial echo"). Speakers, singers and players address themselves to the microphone, and an expert operator in a control-room, following closely the speech or music, continuously makes fine adjustments of the amount of electrical impulse modulating the transmitter to allow for changes of original sound volume, an operation necessitated by the fact that the transmitter is of fixed and limited power. The transmitting gear proper is usually separate from the studio, and may be as far away as 70 or 80 miles, connected with the studio by a special line. Another class of broadcast which is of growing importance is the picking-up at the place of origin of public concerts, operas, plays and public speeches, as well as of ceremonies, crowd noises, countryside sounds, etc. This is done by a portable microphone gear connected, not necessarily by wire, to the control-room; the special interest of these broadcasts to the listener is that they enable him to feel himself as a participant or member of the audience. In the case of music, large-scale performances are often, for psychological as well as acoustic reasons, more successful as "outside" than as studio broadcasts; but, of course, public halls, churches, theatres and opera stages, open spaces and so on, all present special acoustic problems which have to be solved according to the special circumstances.

Of outstanding importance in the organization of broadcasting is the *simultaneous broadcast*, or "S.B." This involves a system of interconnected telephone lines by which a studio or other place of performance can be connected to as many transmitters as may be desirable or possible. Thus the London microphone may be connected to all stations of the British system for a news bulletin, and immediately afterwards all, or some, stations (London in-

cluded) may be similarly connected to a microphone installed in a Manchester concert hall; or, again, the sound of the sea taken up by microphone on the shore at Plymouth may provide a background for a drama performed before the London microphone and broadcast by Plymouth, London and all other transmitters.

Needless to say, S.B. requires the closest timing and co-ordination over the whole system, and it is carried out most completely and successfully when all the stations of a country are under one management, as in Great Britain. In the United States and Canada the method is practised wherever a distributed network of stations happens to be controlled by a large corporation. In Germany, where provincial feeling is strong, artistic resources well distributed and operation decentralized, S.B. is usually practised only between a main station and its relay stations considered as a group. The "wireless link" (*i.e.*, the substitution of the telephone wire by a wireless telephone system) is sometimes employed in broadcasting where land line facilities are either unavailable or unsuitable.

**Listening Problems.**—The listener's end of the transmission system presents problems of its own. Private receiving sets are divided, conventionally rather than scientifically, into "crystal" and "valve" (vacuum tube) sets. The sounds that they generate in response to the excitation of their aërials are heard either in headphones or from amplifiers, the latter varying in power from small drawing-room instruments to large-scale installations capable of reaching crowds assembled in halls and open spaces. The receiving sets themselves vary in sensitiveness, selectivity and other qualities, according to design, workmanship, nature of aerial and earth employed. The crucial distinction in the nature of sets, though roughly coinciding with that between "crystal" and "valve," really turns upon the distance at which a station can be heard without extraneous interferences accompanying, and more or less spoiling, reception.

There are two distinct conceptions of "listening," from the listener's point of view. On the one hand, there is the desire—which may arise from technical interest or from dissatisfaction with the local programme—to listen to far-away stations. This has produced the long-distance set, which is so sensitive as to be able to pick up 1.5kw. stations as much as 1,000 or 2,000 miles away, but which, from the very fact of this sensitivity, is more or less open both to local and remote electrical disturbances, such as those caused by "oscillation" (re-radiation from a nearby receiving set which, when mishandled, acts as a small transmitter), by heterodyning between stations, by "atmospherics," by harmonics emitted by powerful W.T. stations, by the spark transmitters still largely used by ships, and occasionally by inductive effects, due to alternating-current power installations.

On the other hand, there are the listeners who are content with the programmes of the nearest station (which, as we have seen, do not necessarily depend on that station's own artistic resources) either because they have little or no interest in the technical side of wireless telephony, or because the local programmes are artistically and otherwise satisfying. The interest of such listeners is concentrated upon the programme. The receiving apparatus that they need is simple, easily manageable, and owing to the nearness of the station and the consequent strength of its signals free from extraneous interference (other than purely local troubles such as oscillation).

**International Relay.**—Public interest in the broadcast movement tends to centre itself more and more on the programmes rather than on the means of receiving them. This brings forward new problems and prospects of extending, by co-operation between national, as well as by co-ordination of local and regional, broadcasting stations, the field whence material for alternative programmes can be taken and locally re-broadcast. So far as Europe is concerned, this has been rendered possible by the rapid extension of modern long-distance telephony cables; and, given certain technical conditions, there is no further need to doubt the possibility and desirability of "European" S.B. in which a performance given in, say, Munich could be radiated simultaneously from transmitters in Scotland, Poland and Spain, as well as from the German stations.

## BROADCASTING EQUIPMENT IN ENGLAND AND THE UNITED STATES

1. Interior of a studio at Savoy hill, London, showing ceiling height and draping used for the acoustic effect
2. Marconi beam-transmitting station at Dorchester, England, where there are seven transmitters, three operating to the United States and one each to Japan, Brazil, Argentina and Egypt
3. Early transatlantic wireless receiving instrument on exhibition at Marconi house, London
4. General view of control room at 2 L.O., showing "S.B." board and desk in background, with check receivers on left
5. Senatore Marconi's self-designed coherer, used in early experiments
6. Early type of Morse inker for recording wireless signals on paper tape
7. The transmitter at Poldhu, Cornwall, by which the first transatlantic wireless signal was sent, in December, 1901
8. Control room of the National Broadcasting Company at New York city, during one of the national conventions, showing network hookup ready for complete national broadcast
9. Mixing panel, a switchboard where audio impulses from a number of microphones are collected for broadcasting complete results. This was used by the National Broadcasting Company during the Republican and Democratic national conventions in 1928

FIG. 2.—FREQUENCY RESPONSE CURVE OF AN "A" AMPLIFIER

World-wide broadcasting, on the contrary, involves either an enormous development of telephony lines of the highest grade over regions where maintenance of "repeaters" is difficult if not impossible, or the use of the wireless link, which is not ideal even within the limits of a small continent, and becomes less and less trustworthy as distance increases, strength dies out and parasitical interferences multiply. Thus, the prospect of solving this problem by the means used for local broadcasting has come to be recognized as hopeless. A fresh line of attack upon the problem has been developed, however, in the so-called "short wave" of 60 metres, 30m. and less (frequencies 5,000,000kc. per sec. and over), and by this method it has proved possible to transmit speech and music over the whole world.

**Communal Listening.**—Although in civilized countries of the European type the great majority of listeners are individuals and families grouped round their own hearths, this is not the only form in which the broadcaster's output reaches the public. In some cases enterprising engineers have installed central receiving sets connected by wire to the houses of their clients, who listen on telephones or loud-speakers. A variant of the same idea is that practised on a large scale by hospitals and other institutions and the social importance of broadcasting in this case can hardly be overestimated; in certain countries, indeed, such institutions are exempt from paying any tax or licence in respect of this service. Another form of collective listening is the loud-speaker in hotels, cafés, cinema theatres, open squares, etc.; here the audience is the public assembly, not different psychologically from the ordinary audiences attracted by direct performances—from which indeed they only differ in that the performers are not physically present on the spot. Hence this practice of "rediffusion," if carried on without the permission of the authors and others concerned in the original performance, has been held in many countries, Great Britain included, to constitute an infringement of copyright.

Organized communal listening promoted and controlled by the broadcasters or by local or national administrations is likely to have a considerable future, especially for populations of predominantly rural type. In Russia, for example, it may be said to be the most important branch of broadcasting as practised, the individual listener being of much less account. The loud-speaker may operate in or in front of churches, mairies, schools or the like. A special type of communal listening is the religious service in which the sermon, or sometimes the service itself conducted in some centre, is received and diffused in the smaller and more scattered places of worship, many of which have only visiting clergy. Loud-speakers as such are frequently used to convey the voice of the officiating clergy to distant or acoustically difficult parts of the building.

#### ADMINISTRATIVE ORGANIZATION OF BROADCASTING

It has been indicated that there are two main types of organization handling public broadcasting; the commercial and competitive type and the centralized public-service type; and that the former type tends steadily to approximate to the latter so far as concerns its relation with the public. The same may be said, to a certain extent, of the administration and public-relation side of broadcasting. Given the immense cultural, educational, politi-

cal and propagandist possibilities of the medium, it was unthinkable that Governments should disinterest themselves in the programmes. Accordingly we find control, to a greater or less degree, universally imposed on broadcasting. Under a crude commercial system, this control is slight and negative; while, at the other end of the scale, a despotic or dictatorial Government is inevitably tempted to employ broadcasting for the propagation of its own ideas. Between these extremes lie (a) "goodwill" commercial broadcasting tempered by Government regulation, as in the United States since 1927; (b) systems constituted as commercial companies, but subjected to the continuing supervision of a Government department, and limited as to profits; (c) companies commercial in form, in which the Government holds a controlling interest, as in Germany, Austria and Czechoslovakia; and (d) organizations of the type of the British Broadcasting Corporation or the Danish radio council in which a national broadcasting authority is constituted by, but stands apart from, the ordinary machinery of, the State. The success of an organization of the last type depends essentially upon the public's according to its executives and its traditions a confidence that is independent of its political outlook towards the Government of the day; hence it has usually been instituted as the result of prior experience, successful or unsuccessful, of other forms, and not at the outset.

The executive or internal organization of broadcasting is very similar in all countries, but there is one important divergence of practice that should be mentioned. In some countries the engineering side of the work is wholly in the hands of the State telegraph authority, and the broadcasting organization as a distinct body is limited to the provision and execution of the programmes. In others the engineer service is as much a part of the broadcasting organization as are the programme and the administrative departments. That the question is not a simple one may be gauged from the fact that of the two most highly-developed services in Europe the one works under the first and the other under the second system. In the British view there are many factors, such as engineer interest in the details of studio acoustics and management on the one hand and artistic interest in the control of modulation on the other, that make it undesirable for any hard and fast line to be drawn between the two sides of the work.

In most countries broadcasting organizations derive their revenue from the yield of the licence fees paid to the postal authorities in respect of listening sets, a share of which (varying from 50% to 90%) is paid over to the broadcasting service. In some countries taxes are levied upon the sale of receiving sets and parts, and most broadcasting organizations derive a small subsidiary revenue from the issue of programme journals and other publications auxiliary to their work. Elsewhere no charge is made for the possession of receiving sets, and broadcasting is supported either by advertisement or by subsidy from the radio industry. So far as Europe is concerned this system is generally held to be wanting in the indispensable guarantees of regularity, quality and impartiality, and the general tendency is to adopt the pure licence system. In Italy a part of the revenue of the national broadcasting organization (which is of the British type) is provided from general taxation by way of levies on the communes.

**Public Influence and Public Relations.**—Certain particular aspects of broadcasting considered as a public service call for brief mention. These are its relations with the organized musical life of the community, its specifically educational (as distinct from its general cultural) mission, its religious rôle, its news functions and lastly its place in, or by the side of, political life. The opinion may be ventured that the advent of broadcasting has certainly temporarily, and perhaps permanently, arrested a decline which was setting in in the musical life of the European nations owing to a variety of circumstances, amongst them the enhanced costs of ordinary musical performances, the growing popularity of light, showy and ephemeral entertainment, the development of the cinema and the dance hall, and the effectively diminished incomes of the old leisured classes. Broadcasting has not indeed directly checked or altered these tendencies, but it has compensated them by the universal diffusion of music that a generation ago was quite beyond the reach of the masses, by interpreting that music through its critics, lecturers and journal-contributors, and often by performing works that in existing conditions private promoters cannot afford to mount, either because of the magnitude of the work or because of its relatively small "drawing power" from the commercial point of view.

On its strictly educational side, broadcasting addresses itself to two main classes—the schools, in which listening is "communal" and the instruction given is amplified by the teacher on the spot, and the adult student, who may be an individual or a member of a study-group. Opinions differ as to the relative importance of broadcasting in the two cases. In Great Britain, for example, the school side was dealt with first, adult education being a later development, of which the full potentialities can only be realized under a system of "alternative" programmes. In Germany, on the contrary, adult education took precedence, and a special service with a station of its own was created for its purposes, while Austria provides courses of very varied kinds, often of an advanced character, in its ordinary programmes. Broadcasting is also used for keeping scattered professional men in touch with progress (e.g., country doctors in Poland), for giving primary education to children in mobile homes (e.g., of Dutch bargemen) or scattered outside school range (e.g., Russia). A service of particular value is that of scientific instruction for agriculturists. Languages are taught by nearly all broadcasting organizations, and the radio movement has considerably enhanced public interest in the synthetic or international languages.

The part played by broadcasting in the religious life of the communities varies from country to country according to its creeds, the relations of Church and State, and other factors; but there are few countries in which it does not exist. In Great Britain a definite policy of broadcasting a simple form of service and addresses without sectarian bias was adopted from the first, agreement having been obtained between the accredited representatives of the chief Christian Churches as to common fundamentals. In countries predominantly Roman Catholic, on the other hand, religious broadcasting has only been accepted with a reserve, though rarely excluded altogether, and in Holland facilities are shared between the different communions, each being free to propagate its own tenets without regard to the others. More generally fears have been felt that the ability to receive religious services at home would deplete the congregations of the Churches themselves. Experience in Great Britain has not justified these fears, and any loss to the Churches on this score is more than compensated by the spread of their influence over many hundreds of thousands who do not usually attend their services, as well as by the value of the religious broadcast to invalids and aged persons.

The relation of broadcasting to the press and other sources of public information is necessarily an intimate one. To a certain extent they are competitive, and this fact has created many difficulties for broadcasters which only time can wholly remove; but from the wider standpoint of public utility it is easily seen that they are rather mutually complementary than antagonistic. News as transmitted by the broadcaster is brief, oral and non-recorded, and in the nature of things it cannot be surveyed as a page is

surveyed by the reader in search of matter that concerns or interests him. The descriptive broadcasting of races, ceremonies, etc., during the occurrence itself, on the contrary, justifies itself as "actuality" and the news element in it is incidental. It is between the spoken and the printed information *at second hand* that the question here considered lies, and the answer to it is probably that the two services will develop side by side, the rôle of the former being to relate bare facts in the briefest possible form, and that of the latter to amplify and comment on them.

Broadcasting, which addresses millions in every country nightly by direct speech to the individual in his own home, possesses a wider audience than any section of the press and any part of the older social machinery of communication. This fact has its advantages and its dangers. On the one side the leaders of the political and economic life of the community are enabled by it to make sober personal touch with the people without intermediaries and thus it constitutes a means of civic integration unparalleled since the days of the Greek city-state; on the other side, the temptation to direct the machinery with a bias is correspondingly great. At first, therefore, the general practice in countries where broadcasting is centrally controlled was to exclude all controversial matters (other than Government statements, broadcast as such without involving the broadcaster's responsibilities towards his public). Experience, however, has shown that this negative neutrality is insufficient and incompatible with the high rôle of broadcasting as well as with the modern conception of citizenship, and opinion tends more and more to the view that the treatment of controversial subjects (under proper safeguards as to impartiality and moderation) is a proper and necessary part of the function of a broadcasting service.

### AMERICAN SYSTEM

In the United States broadcasting has been developed by private enterprise, with a minimum of Government supervision. This freedom from restraint, while at times giving rise to unsatisfactory conditions, has encouraged competition and has doubtless been an important factor responsible for the rapid growth which has taken place. There is complete absence of any restriction or hindrance to the ownership and use of receiving apparatus, in that no licences are required and there are no fees to be paid. Since there is no financial support for the broadcasting of programmes, derived directly from the listeners through the payment of a fee, other and less direct sources of support have been relied upon. Private enterprise has been forced to find its own means of economic justification and this has added a further element of competitive effort to the development of the industry.

### HISTORY OF DEVELOPMENT

The first experimental attempts at the broadcasting of music by radiotelephony were made in the United States as early as 1916, notably by Dr. Lee De Forest. Further experiments by others, particularly in 1919-20, led to the establishment in 1920 of the first broadcasting stations for commercial exploitation of the new idea. One of the earliest and most successful of these stations was KDKA at East Pittsburgh, Pa., owned by the Westinghouse Electric and Manufacturing Company. The popular interest engendered in the territory around Pittsburgh by the broadcasting of presidential election returns, and subsequently of musical programmes, made evident the possibilities of profit in the manufacture and sale of receiving equipment. This has subsequently proved to be one of the two major sources of financial support for broadcasting activities in America.

The fame attained by the organizations operating the first broadcasting stations, as a result of popular interest in the novelty, brought clearly into view the second major source of financial support, viz., the realization of valuable advertising by the broadcaster. This was something which appealed not merely to manufacturers of electrical apparatus but to business men in general. Owing to the resulting rush into broadcasting activities the field became so crowded as to require organized action.

**The Position of the Government.**—When broadcasting became important there were in force, in the United States, the London International Radiotelegraph Convention and two federal laws, all framed, eight years before, in 1912. These aimed primarily at regulating the maritime use of radiotelegraphy, particularly at promoting safety of life at sea. The administration of national radio affairs relating to commercial stations was entrusted to the Department of Commerce, and the secretary of Commerce was given certain power to make regulations. But the extent to which the law gave the Executive authority was problematical.

In order to obtain advice as to the problems needing Government action, the secretary of Commerce, Herbert Hoover, endeavored to bring those interested into accord through the agency of general conferences. On Feb. 27-28, 1922, he called together, in Washington, a group of men representing various broadcasting interests and including representatives of Government departments and of the public at large. At this time there were only about 50 licensed broadcasting stations. Yet by the time of the Second National Radio Conference, March 20-24, 1923, the number had risen to about 550. These stations were crowded together into narrow wave bands, and conditions of interference had become intolerable. The conference divided itself into committees which brought forth recommendations dealing with such matters as increasing the frequency band allocated to broadcasting to include all the range from 550 to 1350kc. (wavelength, 545-222m.), the classification of stations in regard to the quality of service rendered, and the establishment of a geographical zoning basis for frequency assignments to reduce interference. The Department of Commerce put into force regulations which broadly carried out the recommendations of this conference.

**Commercial Boom.**—During the season 1921-22 the sale of radio receiving sets and of component parts for use in home con-

struction of sets began a "boom" which was presumably responsible for the big increase in transmitting stations during 1922. A large number of radio companies came into being and many speciality manufacturers began to make radio parts. Crystal sets and regenerative vacuum tube sets were in most general use.

Many of the broadcasting stations established during 1922 were operated by radio dealers and manufacturers for the purpose of stimulating receiving apparatus sales in their localities. A classification made in February 1923 shows that about half the stations licensed up to that time were associated with radio or electrical concerns. Next in importance came educational and religious institutions, newspapers and publications, and department stores. The greatest mortality rate was among stations operated by radio and electrical concerns. This indicated the effect of the advertising idea in broadcasting. More powerful stations, sending better programmes, were being financed by organizations not profiting from the sale of receiving equipment.

In response to the popular demand for news and information about radio, newspapers began to print announcements of radio programmes. "Radio pages" and special Saturday and Sunday radio supplements were established which carried, in addition to radio advertising, technical information and instructions for building apparatus, news about radio artists and studios and critical comment on radio performances. Several magazines were established to meet the demand for interesting things to read about radio, and to give directions for home-built sets.

Public education, through individual experience and the flood of printed matter, combined with the improved quality of broadcast programmes, engendered a demand for better receiving equipment and for the greater availability of loud-speakers. The high frequency amplifier type of receiving set, particularly one design named the "Neutrodyne," and the super-heterodyne type of set,

began rapidly to displace the regenerative type, which had proved to be such an obnoxious source of interference in closely settled communities that popular opinion demanded the discontinuance of its use.

**Interconnection of Stations.**—The first use of wire telephone lines in 1922 for interconnecting a station in New York and a station in Chicago, to broadcast simultaneously a description of a football game, introduced a new idea into radio broadcasting. The popular interest had run largely toward receiving distant stations.

FIG. 4.—FREQUENCY RESPONSE CURVES OF A LAND LINE WITH AND WITHOUT CORRECTOR CIRCUITS

The two curves show improvement following the use of line correctors. The lower curve shows response of an uncorrected line at various frequencies, while the upper curve is the frequency response of the same line after corrector circuits have been used

The use of a long-distance telephone line to bring programmes of special interest into the field of local reception at a number of places was of evident value in broadcasting features of national appeal. Furthermore, the use of wires offered a commercial possibility of economic and cultural importance. Performances by leading artists at a centrally located station studio could be sent out to other stations. Smaller stations could afford to offer programmes, obtained by wire, of much greater excellence than those they could produce for themselves. A regular interchange of programmes by wire was initiated between WEAf in New York and WCAP in Washington, D.C., and subsequently other stations were added to the "chain." For special features of national importance large groups of stations were temporarily interconnected.

Station WEAf was established in New York by the American Telephone and Telegraph Company for the purpose of offering broadcasting facilities on a time rental basis to all who wished to broadcast. The radio channels had become so crowded by stations that it was difficult for any more to find adequate places and there were many interests which desired to broadcast but did not wish to go into the project so deeply as to invest in a station equipment. "Toll broadcasting," as instituted in this way, was clearly based on advertising value, and the definite undisguised use of radio broadcasting for advertising purposes was started.

While many programmes could be performed in a studio, there were orchestra concerts, political meetings, athletic contests and the like which, by their very nature, could not be transferred to a studio. Telephone wires were brought into use for carrying such programmes from the microphones at the sources to the broadcasting stations and to the central offices, from which they could be despatched by wire to other stations. Attempts were made to utilize short wave radio transmission to relay programmes between stations, as an alternative to the use of telephone wires, but these were not sufficiently successful to be of material value.

**Third and Fourth National Radio Conferences.**—The stage of development of broadcasting and its relation to the Government toward the end of 1924 are well illustrated by the following excerpt from the address of Secretary of Commerce Hoover, at the opening of the Third National Radio Conference on Oct. 6 of that year. "Radio has passed from the field of an adventure to that of a public utility. We have, in fact, established an entirely new communication system, national in scope. At the end of

four years, 530 (stations) are in operation, making radio available to every home in the country. The sales of radio apparatus have increased from a million dollars a year to a million dollars a day. It is estimated that over 200,000 men are now employed in the industry and the radio audience probably exceeds 20 millions of people. In a large sense the purpose of this conference is to enable the listeners, the broadcasters, the manufacturers and the marine and other services to agree among themselves as to the manner in which radio activities are to be conducted. Like the two previous occasions, this may be called an experiment in industrial self-government." At this conference the frequency band available for broadcasting was widened to 550–1,500kc. (wavelength, 545–200m.). This gave a total of 96 channels each 10kc. wide, of which six were by co-operative agreement assigned to the exclusive use of Canadian stations. The largest transmitting sets in common use had an output of 500 watts but the advantages of increasing power were being recognized. The conference recommendations cleared the way for the use of greater power. Stations of 5 to 10kw. were established during the following year and at least two stations (KDKA and WGY) were experimenting with still higher powers.

The desire to broadcast caused such pressure towards increasing the number of stations on already overcrowded channels that when the Fourth National Radio Conference met on Nov. 9–11, 1925, the need for limiting the number of stations to be licensed was one of the principal matters discussed. In spite of the recommendations of the conference against the granting of new licences and the attempts of the Department of Commerce to find a means of permitting more stations to be operated, dissatisfaction of those unable to obtain suitable arrangements increased, until the situation was precipitated by a Chicago station, which, without authority, began to use one of the channels allocated to Canada. The Department of Commerce brought suit in the courts and lost, it being held that the department had no authority to deny licences or to enforce frequency assignments. While the large majority of stations continued to abide by the rulings of the department a number of stations, popularly called "wave jumpers," proceeded to select waves which suited them and to operate on these waves.

**Act of 1927.**—Legislation to provide a more definite and legally constituted machinery for the regulation of broadcasting had been urged for some time and a number of bills had been put forward in Congress. The chaotic conditions brought about by wave jumping hastened the consideration of these bills and as a result the Radio Act of 1927 became a law on Feb. 23, 1927. This act took the responsibility of licensing stations from the secretary of Commerce for one year, and placed it in the hands of a Federal Radio Commission of five men appointed by the President. At the end of a year the administration of the law was to revert to the secretary of Commerce, the commission remaining in existence, subject to call, as a body of appeal. Appeal from the decisions of the commission was to the courts. Thus, the Radio Commission was established as a temporary body to straighten out the broadcasting situation and as a permanent body to act in special cases. The commission was given rather broad powers to classify and license stations; to assign operating frequencies; to determine locations and operating times and powers of stations; to establish areas of service; to make regulations to prevent interference; to regulate chain broadcasting stations; to hold hearings, summon witnesses and compel production of documentary evidence. The licensing authority need grant a licence only "if public convenience, interest and necessity will be served thereby." This put a stop to the unchecked increase in the number of stations which followed the Department of Commerce's defeat in the courts. The commission set about improving conditions by changing the frequency assignments of certain stations, and by persuading some stations to combine or to divide the time of use of channels they used in common.

#### BROADCASTING AS A BUSINESS

One element of importance in advertising is the number of possible customers it reaches. The value of combining the total

FIG. 5.—FREQUENCY RESPONSE CURVE OF EXPERIMENTAL TRANSMITTER (LOW-POWER MODULATION) STATION DAVENTRY 5GB, ENGLAND. FROM 1927 THE BRITISH BROADCASTING CORPORATION ADOPTED LOW-POWER CHOKE MODULATION FOR ALL TRANSMITTERS. THE AERIAL AT DAVENTRY IS 300FT. HIGH

broadcasting idea with the chain broadcasting idea, to increase the audience and thereby to justify the expense of better programmes, was self-evident. WEAf, the pioneer toll broadcasting station, being owned by the telephone company which also operated the long distance telephone service of the country, naturally served as an important centre for the development of commercial chain broadcasting. Arrangements were worked out whereby the cost of such service could be distributed equitably between the programme sponsor and the individual chain stations using the programme. For advertising programmes the individual chain stations received a portion of the chain rental charges paid by the advertiser. These stations could also obtain, by paying a fee, non-advertising programmes supplied by the central management of the chain. This chain gradually grew, until regular nightly interconnection of a number of stations for certain hours became the rule.

In November 1926 the National Broadcasting Company, organized by the General Electric Company, the Westinghouse Electric and Manufacturing Company, and the Radio Corporation of America, purchased WEAf and undertook the management of WJZ and WRC owned by the Radio Corporation of America. The chain broadcasting activities centring on these stations were continued and expanded.

An interesting sidelight on the development of commercial toll broadcasting through chains of stations is furnished by a rate card issued in 1927 by the National Broadcasting Company. This gives the rental cost per hour, between the hours of 7 P.M. and 11 P.M., for the use of 15 stations reaching from the north-eastern section of the United States as far west as Chicago and as far south as Washington, D.C., as \$3,770. This chain of stations is called the "red network." A "blue network" of nine stations covering a similar territory is offered at \$2,800 per hour. There is a mid-western group of six stations at \$1,140 per hour, and a southern group of four stations at \$750 per hour, either or both of which can be combined with the red or blue networks. A "Pacific coast network" of five stations operated from a San Francisco studio rents for \$1,100 per hour. Discounts are given for long contracts and for use at less important times of day. Of this entire list of 39 stations only one is owned by the National Broadcasting Company. The chains are formed by contractual agreements, the company acting as a sort of booking agent. Other chains than those managed by the National Broadcasting Company are being organized.

**Patents and Copyrights.**—During the boom period of radio broadcasting many companies and individuals started the manufacture and sale of receiving sets and parts with small regard for the infringement of patents. With the number of patents running into thousands it was a difficult task even to determine what patents might be infringed by given apparatus. In 1920 and 1921 several large electrical and communication companies which, taken together, controlled an important group of radio and other communication patents, entered into a cross-licensing agreement

whereby each of the companies was enabled to proceed in its field with a satisfactory patent situation. A considerable number of manufacturers and groups of patents were outside this arrangement but, after a period of negotiation and some litigation, licences were extended to the larger independent manufacturers under royalty agreements, and in 1927 it was generally possible for a responsible manufacturer to equip himself with such licences as would ensure him the right to put on the market receiving equipment of modern design.

The question arose as to whether the performance of a musical composition before a microphone in a private studio, so that it was broadcast by radio, constituted an infringement of copyright. The American Society of Composers, Authors and Publishers championed the cause of the holders of copyrights, and ultimately established a recognition among broadcasters of the right of the copyright proprietors to compensation for the use of their compositions. There was discord over the matter of equitable rates of compensation, but by 1927 this seems to have been adjusted in most cases through private negotiations.

**Effect on Other Industries.**—The rapid introduction of loud speakers and the improved performance of apparatus soon brought the quality of reproduction of speech and music by radio to a greater stage of perfection than had been attained by the phonograph. Although the sale of gramophones was seriously affected, the effect was to regenerate the disc machine. Many of the mechanisms and principles perfected for telephony and broadcasting were utilized, and improved gramophones were developed which came upon the market just as the novelty of radio was beginning to wear off. Combinations of gramophones and radio receiving sets in a single cabinet were also offered.

Some industries have benefited greatly from broadcasting; for example, the manufacture and sale of electric batteries. Previous household use of dry cell batteries was restricted chiefly to flashlights, door bells and the like. There are now large sales of such batteries for radio sets, although the use of so-called battery eliminators has tended to displace them. In general radio has tended to popularize and familiarize electricity and electrical equipment.

**Programmes.**—Beginning with gramophone and piano music and instrumental and vocal solos, the programme field has expanded to include such diverse affairs as symphony orchestras and the sounds of animals in a zoo. One important tendency has been for stations to develop a set of recurring programme features which come at the same time each night; for instance, dinner concerts around 6 to 7 P.M. and dance music from restaurant orchestras in the later evening hours. Many users of toll broadcasting stations give their programme once a week, at the same day and hour. The broadcasting of short plays written especially for the radio and adapted to performance in a studio has met with some success.

**Business Progress.**—The phenomenal expansion of the radio broadcasting business which took place in 1921 and 1922 caused

over-extension among many concerns and brought an inevitable reaction which was felt particularly in 1925 and 1926. A selected group of radio company stocks which was valued, in December 1924, at about 160 millions of dollars, had fallen to 65 millions by July 1926. There were many failures among the smaller concerns and the retail market was so flooded by manufacturers' over-production that many sets were sold for far less than their original price. This experience, as a whole, was not entirely a detriment to the industry, since it forced out unstable or ill-managed concerns and caused the consolidation of others, while at the same time it tested and proved those concerns which came through it successfully. Since then the manufacture and merchandising of receiving equipment have reached a firmer basis.

Broadcasting, as an activity of value to the public, seems firmly established, but many broadcasting stations have not yet reached a permanent basis of financial stability. It is still problematical whether advertising and the sale of radio equipment will furnish most of the funds necessary to support the transmission of programmes, or whether other means of support will also be important.

**Organizations.**—The manufacturers have a Radio Manufacturers' Association and a radio division in the National Electrical Manufacturers' Association. Both of these are active in standardization work. Among manufacturers and dealers there are numerous radio trade associations. The National Association of Broadcasters interests itself in legislation and in general investigations for the benefit of its members, which include a majority of the broadcasting stations. Through the co-operative efforts of these various associations and other interests, radio fairs or shows are held for the exhibition of equipment. Large annual radio shows are held in New York and Chicago.

**Superpower Stations.**—The trend in the use of higher power stations is well illustrated by the case of WJZ. This pioneer New York station late in 1925 moved its operations to a point in New Jersey about 30m. from New York city and began using 50 kilowatts. The combination of high power with a location outside congested areas, to avoid "blanketing" important groups of listeners with excessively loud signals, has been adopted also by other stations which have materially increased their power. Experiments in the use of powers as great as 100kw. have been made by station WGY of the General Electric Company at Schenectady, N.Y. High-powered American stations operate in the same general frequency band with lower powered stations. There is nothing analogous to the European stations operating at lower frequencies (longer wave-lengths).

**Future Tendencies.**—To predict the future of broadcasting in America would be hazardous, but certain tendencies may be indicated. While the possibilities of educational and news broadcasting have not been fully exploited, it seems certain that the amusement feature will continue to be dominant. There are many technical improvements in sight which may be counted on to improve the quality of service rendered to listeners. Added features of novelty are being experimented with, such, for instance, as the broadcasting of pictures, cartoons and the like, for facsimile reproduction in the home, by suitable attachments to broadcast receiving sets, and there are even those who prophesy that the visual broadcasting by television, which has already been crudely demonstrated, will before many years become of practical importance.

### TECHNICAL ASPECTS

The wireless telephone, which is the basis of all wireless broadcasting, first became a practical piece of apparatus after the invention of the thermionic triode (see THERMIONICS) during the years 1912-14. It was developed particularly for war purposes between 1914-18. Certain wireless telephone stations were erected before the World War and in non-belligerent countries during the war, and were designed chiefly for broadcasting special sorts of

news. In Feb. 1920 experimental telephony transmissions were carried out in England on a frequency of 150 kilo-cycles (kc.) per second (wave-length, 2,000m.) and using a power of about 15 kilo-watts (kw.) in the aerial. These tests were withdrawn on account of alleged interference with other services. Contemporaneously with this development a station in Pittsburgh, U.S.A., heralded American broadcasting, which has been in active operation since that period. A Dutch station at The Hague, PCGG, transmitted broadcast programmes sporadically during the years 1920-22, but the station, for which private subscription was from time to time raised throughout Europe, eventually closed down. Certain German stations were during this time transmitting news and weather reports, and Dutch bankers used a telephony station for immediate quotations of market values. Early in 1922 the Radio Society of Great Britain obtained permission to transmit a programme of music and entertainment for half an hour in each week from a  $\frac{1}{2}$ kw. station. This station, 2MT Writtle, was the first station to do regular and scheduled broadcasting in Britain. The British Broadcasting Company started officially in Nov. 1922, but since August of that year a station, 2LO, located on the roof of Marconi house, had been radiating occasional experimental transmissions simultaneously with Writtle. When the B.B.C. started it absorbed 2LO, which became its London station, and also 5IT (Birmingham) and 2ZY (Manchester) operated at that time for the B.B.C. Development in all countries was rapid; during 1923 several European broadcasting stations began operations, and in 1928 there existed over 200 active broadcasting stations in Europe, and from 400-600 stations in the United States.

**First Principles.**—The underlying technique of broadcasting involves a wireless telephone transmitter radiating electric waves nearly equally in all directions, and any number of receivers able simultaneously to detect the intensity of such waves. These waves (in general, of frequency from 1,500 to 150kc. per sec.) are modulated in intensity by any sound desired to be broadcast and these modulations are detected in a receiver. The modulation of the electric waves involves a microphone, which, when acted upon by sound waves, converts the varying pressures of the surrounding air into correspondingly varying electrical pressures. These electrical pressures may be amplified, from their original relatively feeble value, to modulate, in the broadcasting transmitter, the intensity of the power (which is maybe 0.2, 1.0, 4, 10, 30 or 50kw.) of high frequency electric currents in the transmitting aerial. This modulation of the high frequency aerial currents causes a sympathetic modulation of the radiated electric waves. The electric waves falling upon any receiving aerial, adjusted to give the most efficient response, cause high frequency currents to be set up, which, when detected, produce currents copying to a greater or lesser extent the original microphone currents. The receiver currents are made to move a diaphragm in the telephone or loud-speaker which, with action inverse to that of the microphone, produces pressures in the surrounding air making a recognizable imitation of the sound acting upon the distant microphone.

Distortion of the original electrical impulses may take place in each of the necessary energy conversions, and it is important to make each conversion as distortionless as possible. Sound contains a combination of frequencies from 20 to 15,000 or even 20,000 vibrations per second. The response of the human ear varies with individuals and many ears are insensitive to sound vibrations above 10,000 periods per second. In the reproduction of the human voice, for naturalness and intelligibility and for the giving of an adequate sound picture of an orchestra, the human ear is contented with reproduction if every frequency from 50 to 10,000 vibrations a second is present in its right proportion. The problem, as it concerns good quality reproduction, is to produce an electrical system, from microphone to loud-speaker, which gives an equal response to every equal energy value of frequency between the limits stated above. This is far from easy, because successive errors add in cascade and there is a remarkable tendency for every piece of apparatus involved in the chain to respond to the middle frequencies (500-1,000 periods per sec.) to which the ear is most sensitive. This gives the "snarly" quality associated in some degree with almost all forms

by armature movement may be involved by a change of capacity, a change of movement of a conductor in a magnetic field, or a change of resistance in a direct current circuit. The excellence of a microphone may be judged in terms of its response characteristic, and its degree of background noise. The response characteristic of a microphone is measured firstly, as to its ability to give equal electrical response for equal sound wave pressure at any frequency between the limits of the audible range; and secondly, as to its capacity to give, at any frequency, proportionality between input sound pressure and output electrical response. Every microphone has an intrinsic background noise caused by minute changes in the necessary polarizing current with or without the hiss of the amplifier valves. Microphones must be compared for background noise at a given sensitivity.

A perfect response characteristic must involve a complete absence of mechanical resonance within the range of frequency considered. This is not easy, as every armature tends to resonate at some (audible) frequency. Carbon and condenser microphones have been constructed with a view to eliminating resonance by using a diaphragm stretched to have a resonance above the audible limit. A magnetophone, invented by A. S. Sykes, and developed by H. J. Round, has a flabby annular coil, secured by vaseline to cotton wool pads within an outer circular steel ring which produces the necessary magnetic flux. A carbon microphone, widely used in Europe, invented by E. Reisz, consists essentially of a layer of carbon granules, which, if made sufficiently thin, has a resonance outside audibility. Flame microphones are not widely used and may suffer from a resonance in the electrodes. Light sensitive microphones usually involve a moving mirror of some kind for changing the illumination on a light sensitive cell. Moving mirrors tend also to have mechanical resonance.

Broadcasting microphones having excellent response characteristics are extremely insensitive compared to ordinary commercial types (as used on ordinary telephones) in which resonance can be permitted, and their electrical output has to be amplified considerably before it can be used efficiently for transmission by telephone lines to a nearby control room or distribution centre. There may be ten or more studios in a broadcasting headquarters, and therefore the studios may be, even in the same building, a relatively long way from the control room (*q.v.*). The currents generated by the microphone are extremely feeble and therefore liable to be interfered with by induction from electric power and lighting circuits if long leads be used. Amplification is therefore divided into two halves, the A amplifier, located as closely as is convenient to the microphone, the output from which goes eventually to the B amplifier, situated in the central control room. The frequency characteristic of such amplifiers, *i.e.*, their response over the audible gamut, must be as even as possible. Connections between the amplifier and microphone and the amplifier and cable for connecting to the relatively distant control room or transmitter must be through transformers. Transformers are necessary owing to the impossibility of matching the impedance of the output or input valve to the cable or microphone. It is not easy to design a transformer giving an equal response over a frequency range of 200:1 (50 to 10,000 periods per sec.), but by using spaced windings, high permeability iron, and resonance at some high frequency by added capacity, a reasonably good characteristic curve may be obtained. (Fig. 2 shows by means of a curve the frequency response of a good modern amplifier.)

(2) **Place of Origination of Programme.**—*Broadcasting studio* is the name given to the specially arranged room in which artists perform for broadcasting. It is of utmost importance to arrange for the acoustics of the studio to be as perfect as possible for its particular purpose. It is usually unwise, in the present condition of the art, to allow a large acoustical reverberation in the studio. In speech, when intelligibility is of primary importance, it is necessary to use highly damped rooms. For music generally a greater amount of reverberation is desirable and even necessary, though a large orchestra and a quartet require different studio reverberation constants. As a practical basis it is best

permanently to reduce the reverberation constant of the studio to something less than that required for most purposes and then, in some mechanical or electrical way, to add synthetic reverberation. Changing the reverberation of the actual studios, where each may have to be used indifferently for all sorts of different performances, is not practical.

The usual way of reducing the reverberation of a room has been to cover the walls and ceiling with drapery, but, though this is satisfactory in principle, it is ugly and insanitary. The British Broadcasting Corporation and the National Broadcasting Company of America have made practical attempts to do away with drapery. The later B.B.C. studios have their walls covered with a hard paper backed by felt, while embrasures and deep bays prevent high acoustical frequency reverberations. A thick carpet covers the floor and the ceiling has movable draperies. The American organizations employ a form of aero concrete. In British practice artificial echo is introduced by using two microphones, one of which is connected through amplifiers direct to the transmitter, whilst the other is connected through a separate amplifier to a loud-speaker installed in a room with a high degree of reverberation. The loud-speaker in this room faces a microphone, the currents from which are injected into the direct transmitter circuit. The amount of echo current from the echo microphone is directly controllable by a handle, and therefore the extent of superimposed echo may be varied conveniently according to the type of item being broadcast.

In Great Britain approximately 20% of the programme hours is supplied from outside sources, such as church services, public gatherings, theatres and restaurants, etc. In the case of the transmission of a concert from an outside hall it is often found that the acoustics of the building are different from those of a studio, and the best results can only be obtained by experiment. As this is done at a rehearsal before the transmission it is necessary to estimate the changes in reverberation which will result when an audience is present. At the same time it is necessary to adjust the balance of the transmission by the relative placing of soloists, orchestra and microphone, so as to obtain a proper balance. The outside broadcast engineers install their apparatus, consisting of microphones and A amplifiers, wherever and whenever it is required. Connection to the distribution centre of the broadcast organization is made by land line. Where it is necessary for the microphone to be moving during the transmission, as in the case of a running commentary of the Oxford and Cambridge boat race, lines cannot, of course, be used, and connection has to be made to some stationary point by means of a wireless link. In this instance the A amplifier would be replaced by a low-power wireless transmitter the emissions from which can be received at some stationary point and the transmission then passed to the distribution centre.

(3) **"Mixing."**—The development of the dramatic programme, with attendant incidental music and effects, has necessitated the frequent use of several studios simultaneously. It is not feasible with small studios to concentrate artists, chorus, orchestra, effects, producers, etc., together; several studios must be employed, and the transmissions from each of these combined in a "mixing" room through which the outputs of all studios pass on their way to the central control room. Signalling circuits are installed between all studios and the mixing room, between the mixing room and the control room, and between the control room and all the studios. The outside broadcast circuits can also be led through the mixing room as it is sometimes required to superimpose external effects on a studio programme. The mixing room is also connected by a land line to a wireless receiving station and here any distant transmitting wireless station, permanent or temporary, may be picked up and re-broadcast over the normal national broadcast system.

(4) **The Central Control Room.**—At this link in the chain of transmission two definite functions are fulfilled; viz., that of adjusting the level of low frequency energy to modulate more or less the transmitter high frequency currents, and that of distributing the programmes to one or more transmitters, centres or listening points.

The first of these functions, that of controlling the intensity of output to the local and other transmitters which are taking the programme, is necessary for the following reason: a brass band gives a volume of sound output hundreds of times greater than a person whispering or a distant nightingale; if the sensitivity of the microphone or its amplifier were not varied, either the listener would never hear the nightingale or the brass band would vastly overmodulate the constant-power transmitter; during the musical items, if the pianissimo passages were not amplified and the fortissimo passages not reduced a little on the amplifier, an inferior sound picture would be rendered even on the best receivers.

The second stage of amplification in the broadcast chain is situated in the control room, and is known as the B amplifier, which is designed for variable sensitivity, and it is the duty of the "controller" continuously to control the intensity of the transmission with the idea of giving to the listener the best possible sound picture of the original. A point on which much variety of practice and opinion exists is whether this control of volume should be in the hands of engineers or of artists. The advantage of the latter is that a score can be followed with a view to the anticipation of a forte passage and a consequent slight reduction in time to prevent over-modulation, and vice versa for the prevention of under-modulation during pianissimo passages. The eye, and not the ear, must be the criterion for the accurate judgment of the effects of controlling, and each "control" amplifier is equipped with two meters—one to show a maximum which must not be passed, the other to show the volume being radiated at any instant. It is necessary to have two instruments, because the permissible maximum for a given volume is not the same with different voices, instruments, studio acoustics, etc. In addition, the depth of modulation at every instant throughout the transmission is checked mechanically on a recording modulation meter to show up any faults due to the human element.

The second function of the control room is to provide a means of handling conveniently the distribution of the one or more programmes to those transmitters which are sharing the transmission with the local station. In practice the problems of programme building are simplified enormously by the ease with which stations can be made to exchange programmes and by the reduction to an absolute minimum of the time taken in making changes. The system depends on the use of a multiplicity of relays, amplifiers, alarms, line terminal switching, etc. Finally, the engineer in charge of the control room is responsible for the maintenance of all transmission logs (in the case of the British system accurate to a second) and for the cutting and timing of the transmission generally.

(5) **The Land Line and Wireless Link.**—It is necessary to have as many stations as there are channels of free ether available. If an event or performance of nation-wide interest is to be broadcast it is necessary to allow all subscribers an equal chance of hearing. This is made possible by using telephone lines or cables to connect the point at which the event takes place, first to the nearest distribution centre in the broadcast system, and thence to all stations that require to take the programme. This is called *simultaneous broadcasting* in Britain, or *chain broadcasting* in the United States. All lines of great length introduce an impedance which varies with different frequencies. This means that a microphone system giving a perfect response characteristic will, if connected to a long line, produce at the end of that line a distorted output unless precautions are taken to equalize inherent distortions. There are in general two types of line—overhead and cable. The former is the familiar type suspended on porcelain insulators carried on poles, while the latter is buried in trenches. An inch diameter buried cable, for instance, may carry 150 circuits. The overhead line would appear to introduce less distortion than the cable because its distributed self-capacity is lower than that of the buried type. Cable can, however, be treated to give a good characteristic, *i.e.*, less differing impedance to different frequencies, by a system of loading. Light loaded cables, which are, however, more expensive, have characteristics suitable for broadcasting work.

The currents in any long line attenuate (steadily decrease as they proceed away from the original source), but this effect is more rapid in the case of a cable than it is with open or overhead lines. This attenuation can, however, be overcome by the use of thermionic amplifiers placed at regularly spaced intervals along the line. These are called "repeaters" and the points at which they exist "repeater points," and such are extensively used in

modern trunk telephone routes (*see TELEPHONE*). The commercial type of repeater, which enables a conversation in both directions to be raised in level, is both unsuitable and unnecessary for broadcasting. The broadcast repeater need only work in one direction, but must maintain an even response characteristic. Apart from the problem of attenuation and the precautions which are taken to overcome it, every line will introduce some distortion by cutting down certain frequencies in favour of others. It is therefore essential to employ a frequency response correction by the termination of lines at repeater points and at their final terminations with a filter containing concentrated inductance, capacity and resistance.

FIG. 7.—ATTENUATION CURVES, WHEN 1 KILOWATT IS RADIATED AT DIFFERENT FREQUENCIES

Owing to the fact that the cable cannot be used for connecting different continents separated by wide oceans, the "wireless link" should play a part in long range broadcasting. Stations using very high frequencies (15,000 to 7,500kc., 20 to 40m.) can be picked up over ranges equal to the maximum distances existing on the earth. Unfortunately the solution of the problem of sufficiently satisfactory reception for re-broadcasting purposes is incomplete; there is not a guarantee of service on short waves although they offer possibilities for future success. Since 1923 America has sent out programmes from short wave stations which can be heard, conditions permitting, all over the world. Usually reception is too inferior to be compared to that existing with the national services from local stations though occasionally programmes from America have been re-broadcast in Britain. Early in the year of 1927 Holland started sending short wave transmissions which have been heard sporadically throughout the world, while later in the same year the British Broadcasting Corporation began to radiate regular daily test transmissions from a short wave station and transmitted the Armistice day programme on Nov. 11, 1927.

(6) **The Broadcast Transmitter.**—The general principles and practice of wireless telegraphy and telephony transmission are dealt with in the articles WIRELESS TELEGRAPHY and TELEPHONE, and therefore discussion of this point will be confined to essentials. The basic system of modulation for broadcasting transmitters is known as "choke control." In this system the power supplied to the oscillation generator, which generates the high frequency currents in the aerial for radiation, is varied in sympathy with the amplified microphone currents by the action of control valves. As in the case of other links in the broadcast chain, the problem is principally one of achieving a perfect frequency and volume response characteristic, *i.e.*, proportionality between the limits of maximum and minimum modulation and an equal modulation at all frequencies for any given input volume. Economy in power, ease of maintenance or accessibility, and trustworthiness are also important factors. Two systems of modulation make use of choke control, the one modulating the aerial currents at high power and the other at low power. In the former (used almost exclusively, except by the German administration) the modulation system is in effect a low frequency power amplifier with sufficient power to modulate the aerial oscillations; in the

latter, modulation takes place at low power, whereafter a high frequency amplifier increases the power of the modulated high frequency currents to the desired value. In the case of the British Broadcasting Corporation low-power choke modulation was adopted after 1926 as standard for all transmitters designed and built for them. (Fig. 5 shows the response characteristic of a modern British transmitter of 30kw. working on low-power choke modulation.) In Germany a system is employed in which modulation is achieved by an alteration of the constants of the grid circuit of an oscillation generator. High-power modulation is in use in practically all other countries, such as America, France, Sweden, Denmark, Italy, Spain, etc., while some central European States use the German grid system as well for different stations.

Most antennae systems for a modern installation are half wave-length aeriels supported on steel towers. It has been proposed to abolish the half wave aerial because of its interference-producing qualities at long ranges, but its local advantages in distribution of signal strength cannot lightly be foregone. Modern technique mostly employs aeriels located from 20 to 100ft. away from the transmitter buildings, the power output of oscillations being fed to the aerial via a two-wire feeder. This increases the radiation qualities of the aerial and has no compensating disadvantage.

(7) **The Broadcast Receiver.**—Broadcasting receivers may be of the valve or crystal type. The valve set requires the installation of some power supply, and is essential in areas of weak signal strength or in areas of normal signal strength where only small aeriels can be erected or anywhere for loud-speaker use. (Reference should here be made to figs. 8, 9 and 10, giving crystal 3-valve and 5-valve lay-outs.)

Development in receiving sets, like the various links in the transmission system, is continually towards an even response characteristic, with efficient maintenance, ease of handling, and a sufficient but not too great measure of selectivity. Good quality reproduction is mostly a matter of the power available to work the loud-speaker, though the method of coupling the low frequency stages of amplification and the use of a good rectifier are extremely important. It is unusual, but nevertheless advisable, to provide a power of ten watts to the anodes of the last magnification stage of receivers, though many receivers are supplied with less than one watt. Failure to attain the ideal is chiefly due to the power available from high tension batteries being inadequate; wet or secondary accumulator high tension batteries cannot be used where facilities for recharging are not available. Where electric power mains are already installed the conversion of the house supply to the type required for wireless receivers is sometimes gained at a high first cost. Mains adaptors (*i.e.*, arrangements for taking power from the public electric supply), apart from their technical suitability, give, once installed, a minimum of maintenance trouble to the listener. The advent of the separately heated cathode valve facilitates the use of battery eliminators, while their electrical constants compare favourably with that of the now more common type of valve.

The design of good loud-speakers proceeds apace and some excellent types are available. It should be remembered that no loud-speaker can give good quality if its input is limited or distorted by the receiver. In 1928 selectivity within 100kc. was only achieved at the expense of the frequency characteristic of the receiver, or by the addition of a wavetrap to eliminate the unwanted station. In America, where ten or more stations, separated by only, say, 30 to 50kc., may have practically equal field strengths over an area, some extremely selective receivers have been produced, but their ability to eliminate many stations in favour of one is often only achieved by depreciating the frequency response. In most European countries where distribution in thickly populated areas has been on a single programme basis,

the development of high selectivity without a loss in the quality of reproduction has been retarded. This has permitted greater freedom in the design of high frequency circuits, and the response characteristics which are obtained are excellent. The ideal receiver should produce a square resonance curve 20kc. wide, movable as a whole, without loss of its shape or change in width, over the required frequency gamut of all broadcasting stations. This movement and all other adjustments should be operated simultaneously by one handle, the receiver being efficiently energized from the electric supply.

#### (8) The Distribution and Power of the Transmitters.—

(a) *Service area.* It is necessary to ensure that the programme shall suffer no interruption from extraneous electric waves from whatsoever source. As the distance between the listener and the broadcast transmitter is increased so will the liability to interruption be increased; *i.e.*, as the receiver is located further and further away from a station, the ratio of the required signal to the unwanted interference becomes less and less. This ratio is not a function of the type of aerial nor the type of receiver used by the listener, because if more amplification is used both the disturbances and the broadcast signal are each proportionately increased. If radiation is perfectly symmetrical around a broadcasting station then the rate of decay, or attenuation, of signal strength is equal along any line drawn from the transmitter. Thus an area may be enclosed by a circle within which the signal strength is greater than a certain amount. By common experience in the regular reception of signals of various field strengths, it is possible to estimate service ranges in terms of degree of interruption. Service areas have been defined arbitrarily in terms of field strength, as follows:

| <i>Boundaries in Millivolts per metre</i><br>(a convenient method of<br>expressing strength of signal) |                              |
|--|------------------------------|
| <i>Service Area</i>  | <i>Over 30 mv. per metre</i> |
| "Wipe-out"   |                              |
| A  | " 10 " " "                   |
| B  | " 5 " " "                    |
| C  | " 2.5 " " "                  |

These definitions of service area have been accepted and adopted by the technical committee of the Union Internationale de Radiophonie. Within a "wipe-out" area uninterrupted service can be

FIG. 8.—DIAGRAM OF THE CIRCUIT OF A CRYSTAL RECEIVER

FIG. 9.—DIAGRAM OF A THREE-VALVE, OR THREE-TUBE, RECEIVER  
This receiver employs a screened grid, high frequency amplifier, anode band detector and a five-electrode transformer coupled with low frequency amplifier

guaranteed, unless the interference is produced by listeners themselves producing oscillations in their receiving aeriels. There will be difficulty in a wipe-out area in "cutting out" the local station in order to receive more distant and weaker transmissions from other stations. In an "A" service area very little interruption will exist even in large towns where extensive use is made of electrical apparatus likely to cause a disturbance. In a "B" service area there may be, in a minority of cases, some interference. Crystal reception is possible with good equipment up to the outer boundaries of a "B" service area. In a "C" service area amplification

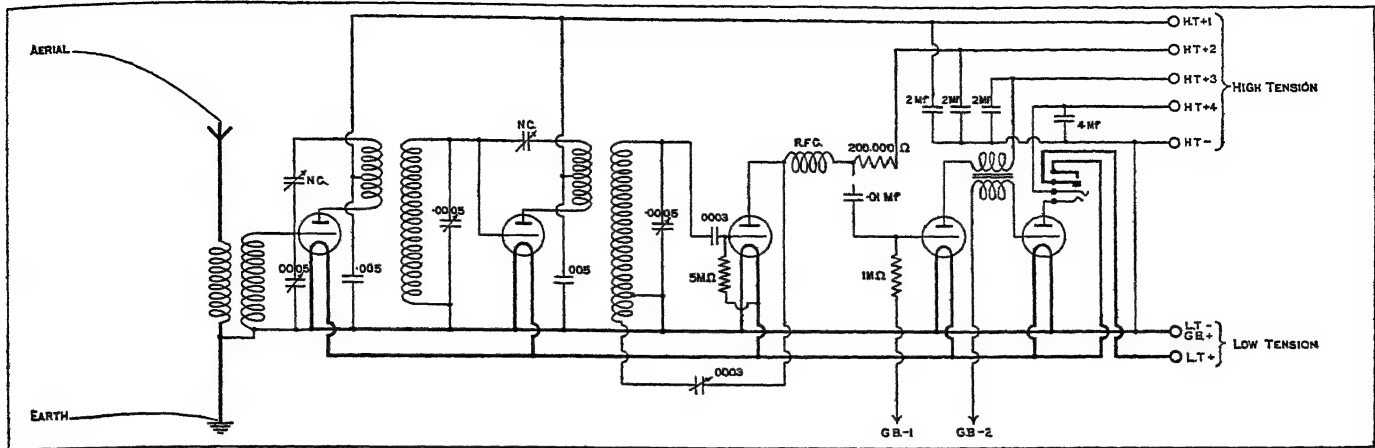

FIG. 10.—DIAGRAM OF A FIVE-VALVE, OR FIVE-TUBE, RECEIVER

This receiver employs two high frequency amplifiers neutralised, a detector, two low frequency amplifiers, one resistance capacity coupled and the other transformer coupled

by valve receivers is essential, and some interruption, depending upon local conditions, is highly probable.

No service area, whatever the power of the station, can be much greater than 100 miles radius, when using frequencies of the order of 1,500 and 500kc. (200 to 600m. wave-length), owing to wide variations of received signal strength after nightfall. This variation of signal strength is called "fading" or "night effect." Fading is believed to be due to the existence of a ray from the broadcasting station which does not travel directly over the earth's surface, but travels upwards and is then bent down from an electrified layer (called the Kennelly-Heaviside layer) in the upper atmosphere. This indirect ray does not remain constant, owing to the momentary variations of the refractive power of the electrified layer; and for this reason the listener has to contend with a constantly changing signal strength which ruins the musical value of the programme. The listener must in fact depend for service upon the direct ray which can only outbalance the reflected ray at distances which are, in practice, seldom greater than 100 miles.

For any given radiated power the extent of service area is affected by three variables: frequency of wave emitted (and therefore wave-length), type of ground around a station and what is found upon it (trees, houses, etc.), and type of transmitting aerial. The higher the frequency the more quickly the direct ray waves attenuate. The use of longer wave-lengths might appear advisable as the waves are less attenuated and the service area for a given power greatly increased. This is true, but the longer the wave-length the fewer the channels available in a given wave-length gamut. For instance, there are 50 channels in the wave band of 200 to 300m., and only one channel in the band of 1,500 to 1,600 metres. The situation with regard to interference by all the users of aether is so serious that very few "long" wave-length channels are available for broadcasting, and at the Washington Conference of 1927 only six channels were allotted for the use of broadcasting transmitters. Waves of frequency above 150kc. (2,000m. wave-length) do not lend themselves conveniently for broadcasting owing to the impossibility of obtaining proper frequency characteristics under efficient working conditions of the transmitting aerial. The ideal system of producing extensive service areas relies upon a combination of long and medium waves. If no other wireless services required the use of the aether, waves of frequency 1,500 to 1,000kc. would be used for low power local services, from 1,000 to 500kc. for regional broadcasting, and from 500 to 200kc. for national broadcasting.

When waves pass over water, or wet, treeless and unpopulated ground, they do not attenuate so quickly as when they pass over ground covered by forests or towns. In fig. 6 a field strength contour map is shown, giving the result of observations for the London station, 2L.O. It will be remarked that the service area is anything but circular, and that listeners, living at equal distances from the transmitter but in different directions from it will not receive the same strength of signal. This is caused by the differ-

ence in attenuations in different directions, due to the various types of obstacle over which the signal passes. Fig. 7 is a family of curves showing the attenuation of field strength when 1 kw. power is radiated at different frequencies over average English pastoral country.

(b) *Interference Between Stations.* Every broadcasting station operates by the modulation of electric waves sent out from its antennae. A more exact mode of expression would be to say that waves are sent out at a frequency  $N_{cw}$  and have added and subtracted from them waves of frequency  $N_m$ , where  $N_{cw}$  is the carrier wave and  $N_m$  the modulated wave frequency. Thus a complex disturbance  $N_{cw} + N_m$  and  $N_{cw} - N_m$  is radiated. Expressing this numerically, if a note of 1,000 periods per sec., e.g., a note of a violin, is to be radiated and the carrier wave frequency is one million, then there are radiated out into the aether waves of frequency one million, one million plus a thousand, and one million minus a thousand. It is the function of the receiver to detect the production of beats by these frequencies so as once more to produce the note of a thousand in the telephones or loud-speakers. The added and subtracted waves are called side bands. As it is desired to reproduce frequencies up to a maximum of 10,000 cycles per second (10kc.) each broadcasting transmitter occupies effectively a frequency spectrum within the aether of 20kc. or 10kc. each side of the carrier wave frequency. If therefore a second station has the frequency of its carrier wave separated by less than 20kc. we should expect the side bands of one to interfere with the side bands of another. This assumes, theoretically, that frequency space must be left for the accommodation of two simultaneous 10kc. side bands in order that they shall not combine to produce less than a further 10kc. frequency.

At the Washington Conference of 1927 it was agreed by the Governments to allocate a frequency band for broadcasting from 1,500kc. per sec. to about 550kc. per sec. (200m. to 545m.). This means that with 30kc. separation between stations, about 30 channels exist for the exclusive use of all the broadcasting organizations. It might be expected that such a number of available channels could be increased by duplication because of the large geographical distance between stations. This is partly true, but even if stations as much as 3,000 miles apart are not separated in frequency by a minimum of 10kc. interference will result during hours of darkness and service areas will be reduced. This means that there exists room for approximately 95 medium-frequency stations if each is to be assured moderately free aether. In the lower frequencies 64kc. have been allocated, giving room for an additional six to seven stations only. It will be appreciated that relatively few channels exist for all the European broadcasting stations, numbering 200 or more.

A solution to the problem has been attempted in Europe by the technical committee of the Union Internationale de Radiophonie which represents approximately 80% of the broadcasting organizations of Europe. A plan was drawn up which gave, of the

channels existing, a certain number for the exclusive use of each nation. The allocation of this number was based upon the area, population and "intellectual and commercial importance" of each nation, the latter factor being calculated upon the number of telephone calls made and telegrams sent in a given year in each country. It was found that there existed far more stations than frequencies. A certain number of frequencies therefore were classified as non-exclusive, to be shared by stations far apart in geographical distance. Such stations have to be content now to give a purely local service, as their service areas are seriously diminished by interference from the other stations with which they share channels. The remaining frequencies were allotted "exclusively" to particular nations for the use of their more important stations, whether such stations were already existing or contemplated. In spite of formal acceptance in 1926, many nations had not by the end of 1927 carried out their part in the necessary readjustment, and conditions were little improved. In 1928, however, many more nations accepted the plan both in principle and in fact.

(c) *Distribution for National Systems.* Broadcasting has grown up in a somewhat haphazard way and knowledge has come in terms of actual experience. So far, all nations have realized that many stations of fairly low power give the most uniform distribution of service area. The system of distribution now existing in Britain is typical of most countries where the responsibility for providing a national service has been vested in one authority. It was built up first by the erection of eight main stations for the service of the principal towns and districts. These stations had "C" service areas of only about 30 miles radius, and therefore left much of the country, urban and rural, almost unserved. Other urban areas were filled up by smaller stations. These small stations are known as *relay stations* because they are linked by land line to some central studio and repeat the programme of a main station. (With a limited income it is not wise unduly to dilute programme revenue, otherwise variation in mediocrity alone results.) The main and relay stations brought practically all urban areas within a "B" service area, and consequently the rural areas only remained uncovered. This was done by one high-power station working on a lower frequency and, with the assistance of the other stations, 80% of the population were brought within the "B" service area of one programme. This involved the use of 21 channels.

This system of distribution was of relatively rapid growth in England as compared with other contemporary organizations and, being temporarily adequate, caused over two million listeners to subscribe to the service. During the years 1926 and 1927 the number of European stations rapidly increased and with their expansion the mutual interference between stations became more serious on account of the limited number of channels available. The once sufficient national distribution was so restricted by interference that it became necessary to build afresh, but with fewer stations of higher power and giving a greater service area per channel.

In Germany, America, France and Spain, where private enterprise alone, chiefly or in part, provides the broadcasting service, stations are found grouped round urban areas and rural areas are comparatively neglected. This is a very obvious development since the stations are supported by advertisement revenue and therefore require to compete with others by covering densely populated areas. Nevertheless the problem of free aether is as acute in the United States as it is in Europe, and the policy which would allow the high-power station to seize for itself what aether it requires, resulting in the consequent survival of the richest organization, is an undesirable solution.

In Britain a scheme, called the regional scheme, has been framed to be gradually put into practice from 1928 onwards. The essential feature of this new scheme of distribution is the use of few, but high-powered, stations so designed and sited as to give a choice of two programmes to the maximum number of listeners. By locating two high-power transmitters at the same point their service areas are made almost coincident so that, given adequate separation between their carrier frequencies, everyone within

their service areas has an equal facility for the reception of both programmes. A method of minimizing interference is to work two stations on exactly the same carrier wave frequency. Researches on this subject made by the B.B.C. from 1926 to 1928 show that, in spite of the fact that the carrier and side bands of each station must interfere, nevertheless good service results from one station at the points where its field strength is greater than five times that of the other sharing its wave, provided each station transmits the same programme. This should allow some economies in aether channels. Already America, Sweden, Germany and Great Britain have made attempts to place such a scheme into practical operation.

See L. B. Turner, *Wireless Telegraphy and Telephony* (1921); W. Greenwood, *Text-Book of Wireless Telegraphy and Telephony* (1925); A. H. Morse, *Radio: Beam and Broadcast, its Story and Patents*; J. Lawrence Pritchard, *Broadcast Reception in Theory and Practice* (1926).

**BROADCAST MUSIC** is one of the most prominent features of all wireless entertainment programmes, alike in Europe and America, as well as, it may be added, in all other parts of the world—Japan for instance—where broadcasting is known. Naturally, however, the mode of procedure adopted in this case and that varies greatly, and it has been thought desirable accordingly for present purposes to deal separately with existing methods and conditions in (I.) Europe and (II.) the United States.

### I. GREAT BRITAIN AND THE CONTINENT

The growth of British broadcasting in its first six years can be most easily measured by the advance in the quantity and the quality of the music transmitted. Music,—of every class, because every degree of taste has to be catered to—formed all along the bulk of the programmes, latterly some 70 per cent. But the first broadcast music was of a very humble order, comparable rather with a parish room entertainment than with a serious concert. In the early days,—the latter part of 1922,—the broadcasting of opera, oratorio, or symphony concert may have been dreamt of; it was certainly not thought of as within the realm of possible achievement.

The first broadcast concert recorded in Great Britain was a garden fête at Hampstead in July, 1922, at which listeners were treated to an entertainment of unconsidered trifles of the lightest type; a note was printed at the foot of the programme, announcing that an organ pipe would be blown before the transmission to assist listeners in the tuning of their receiving sets. During the next four months, various other musical feasts helped to prepare wireless enthusiasts for the first so-called orchestral programme. It was provided by some nine players plus an assisting pianist, and comprised a selection of better class light orchestral music with vocal and instrumental relief. That was in December, 1922. It was a considerable advance upon its predecessors, but it was a slight matter compared with what was to happen in the next few weeks. The British National Opera Company was giving a Christmas season at the Royal Opera House, Covent Garden, and its directors were approached by the British Broadcasting Company (as it then was) with a view to arranging a broadcast from the theatre. On Jan. 8, 1923, Mozart's "Magic Flute" was transmitted with such success that performances of "Hänsel und Gretel," "Pagliacci," "Siegfried," "The Marriage of Figaro," "Faust," "Madame Butterfly," "La Bohème," and "The Valkyrie," followed in quick succession. And a noteworthy feature of that early stage of broadcasting's history is that the performance of Puccini's "La Bohème" had the added glamour of Dame Nellie Melba's collaboration.

The success of broadcasts on so large a scale had the inevitable result of widening the scope of the Company's own musical organization to an extent and with a rapidity that can be only briefly summarized here. The orchestra was increased, for instance, from the nine good men and true who carried the whole burden of the early concerts, by the addition of a Mustel organ which filled in the missing wood-wind parts, and by a cornet and trombone. The next step was to reinforce the Mustel organ by single wood-wind and two horns, together with a contra-bassoon to strengthen the basses. Next, the strings were augmented, and

then the wood-wind; an extra trumpet, another trombone, a harp were added in turn, until a small permanent symphony orchestra of 37 carefully chosen players, with complete wood-wind, brass, and percussion, came into being. The organization is run on the "no deputy" system and can be augmented to 50, 60 or more players selected from a list of regular reinforcements. And, as a permanent chorus was established about the same time, it soon became possible to arrange complete opera and oratorio transmissions as well as concerts of symphonic music: the broadcasting studio became an opera house or concert hall according to the requirements of the programme.

While these changes and developments were going forward in the London studios—the headquarters of British broadcasting, similar organizations were being built up at the other main stations of the company. By the end of 1924 there were eight other towns in England, Scotland and northern Ireland, each of which possessed its own permanent "Wireless" orchestra and choir, conducted by a musician of experience and repute. For the first time in the history of British music, daily concerts were being given on all seven days of the week, by orchestras and choirs capable of undertaking the most serious and important works in practically every branch of music. Light and popular music naturally formed the backbone of the programmes: as interest in wireless spread, the newcomers to the great body of listeners naturally included many thousands to whom serious music was a new thing. A gradually increasing proportion of the best music of every age and country was broadcast, and at least once a week, something of the standard of a symphony concert was broadcast from every station of the company.

Some system was needed, to prevent overlapping and omission, and a scheme was prepared in accordance with which the so-called "standard music" was performed regularly on a definite plan.

Nor was it only orchestral and choral music which was thus carried into most British homes. Chamber music, songs, and instrumental pieces have all been cultivated with the same care and thoroughness. At the London station a special feature was made of contemporary chamber music. Apart from the regular broadcasts of established masterpieces, a series is organized each season with the specific object of presenting to British listeners something of the latest developments in the chamber music of all schools and countries. In that way Great Britain has kept in touch with modern tendencies.

But transmissions of music from the stations were by no means the sole consideration of the Company and, later, of the Corporation. It was soon realized that greater value and interest could be given to the programmes by the broadcasting of public concerts. But here, strong opposition from existing concert organizations had to be faced, so strong indeed that the company had to institute its own public concerts. These were inaugurated by a short season at the Central Hall, Westminster, in the winter and spring of 1924 and 1925. A number of concerts in the provinces were also relayed, notably those of the Hallé Orchestra, Manchester,—which was, incidentally, the first organization to recognize the permanent importance of broadcasting,—the Scottish Orchestra, the Liverpool Philharmonic Society, the Birmingham City Orchestra, and others which were alive to the value of the new service.

During 1924 and 1925, a further series of symphony concerts was arranged by the B.B.C., in the Royal Opera House, Covent Garden. Later, the Albert Hall was tried, with an orchestra enlarged to 150 players, to meet the acoustical shortcomings of that vast auditorium. Eventually, however, the Queen's Hall, whose lessees were originally unflinching opponents of wireless music, opened its doors to broadcasting, and by the autumn of 1927, the real centre of London, as of British music, became also the scene of the B.B.C.'s most important concerts. It will no doubt remain so until such time as the Corporation finds itself the possessor of a concert hall.

Since the autumn of 1928, choral works at these concerts have been sung by "The National Chorus," a voluntary body of 250 picked voices recruited by the B.B.C. from choral societies in the

London area. Its members are all pledged to continue in active membership of their original societies, the B.B.C. hoping thus not only to avoid trespassing, but even to assist the cause of British choral music.

In 1927 the Corporation assumed responsibility for the Queen's Hall Promenade Concerts, which were on the point of coming to an untimely end. With Sir Henry Wood as conductor, the Corporation carried out a series of concerts on the traditional lines, following it in 1928 with a longer and equally successful season. Co-operation with other concert undertakings throughout the country is extending, and in 1928 the Corporation joined hands with several local authorities to found the National Orchestra of Wales, to give regular symphony and popular concerts in Cardiff. Side by side with its development of public symphony concerts, the Corporation has cultivated opera, not only by transmissions from the studios with a repertoire ranging from Monteverdi and Handel to Puccini, Debussy and Schönberg, but also by broadcasts of performances under the management of the International Company at Covent Garden, the British National, and Carl Rosa companies.

To sum up, it is not too much to say that every form of music, in the best form in which it can be heard,—from the Three Choirs Festival or the great cathedral services, through all the range of oratorio, opera, choral and symphony concerts, down to dance music and revues, in Britain, and even, by means of continental relays, abroad, has been, in the first six years of British broadcasting, brought within the reach of every home throughout the country.

(P. P.)

## II. UNITED STATES

When wireless was first considered for amusement purposes in the United States it was recognized that a new set of problems would have to be solved to meet conditions that were very different from those encountered in wireless used for commercial purposes, the only use made of it until that day. It was also recognized at the outset that the most important factor in the broadcasting of amusements would be the transmission of music. Its general appeal and its wide range both instrumentally and in composition gave promise of giving great variety of entertainment. But naturally there was ignorance at first as to (1) what types of music could best be broadcast and (2) what kinds would most readily interest the listening public. One thing, however, was certain, namely, that a far better kind of reception for the listener would have to be developed than had been attained for commercial uses. At this time, those who had devoted their time to wireless were largely engineers and their associates who were primarily concerned with its mechanical problems, but obviously if musical performances were to be introduced this demanded qualified direction and the careful study alike of the technical considerations involved and of the tastes of the public.

In the result, solo singers, male and female, were heard first; then chamber music organizations, such as string quartets and wood-wind ensembles; and finally full orchestras. As to the kind of music chosen it was found from the first that "popular" music made inevitably the widest appeal and further that with the then increasing craze for jazz music, the jazz orchestra was a particularly useful medium for broadcasting purposes; and jazz has remained in a prime position during the years intervening, a fact due both to the popular taste in music and to the exceptionally happy manner in which the typical jazz orchestra lends itself to effective transmission. Those, therefore, who may be disposed to decry the prominence given to this kind of music in broadcasting programmes must find a reason, if not a justification, for it in this fact.

Voices at first presented severe problems, especially the high soprano, which in spite of considerable research and careful adjustments remains still the most difficult kind of voice to broadcast. The contralto voice, on the other hand, is generally satisfactory, the like applying to tenors, barytones and basses. In the case of vocal ensembles the male quartet has proved a far better medium than the mixed quartet, a fact which is accountable for the large number of excellent male quartet performances which

are to be heard in radio programmes to-day. So far as choruses are concerned, it has not been found practicable to broadcast more than from 16 to 20 voices from a broadcasting studio. But successful broadcasts of larger bodies have been made from what is known as a "remote control," that is by placing the microphone in a concert hall when a public performance is being given.

And the same plan has been adopted with good effect in the case of orchestral music, such famous organizations as the New York Philharmonic, the Boston Symphony and the New York Symphony orchestras, to name but three of many, having all been constantly heard in this way. The last-named orchestra has also been broadcast from a special studio in New York in a series of performances separate and distinct from its own regular concerts. In this manner the performances of these great symphonic organizations have been enjoyed by millions of music lovers who would otherwise never have had an opportunity to hear them and so have been enabled to make acquaintance, in many cases for the first time, with some of the most important works of the great masters.

Ranging between jazz and symphony, radio broadcasters have to a certain extent presented music in all other divisions of musical literature as well. Thus chamber music, religious music, operetta and musical comedy have all been represented. In the case of chamber music it is perhaps worth while pointing out that special care should be exercised in regard to the works chosen. For unless the listener to whom chamber music is new finds this music of distinct appeal, he will in no sense be won by it and will inevitably turn his dial, exercising a prerogative which is every radio listener's. Works of a decidedly melodic nature are the safest for broadcasting purposes, as has been established in numerous tests. On the other hand, harmonic subtleties which may come through well enough in concert performances are apt to suffer badly in radio transmission and thus only an imperfect account of a composition of this type is presented to the listener.

In general it may be said that there is certainly a wide field for all types of programmes and that the future of broadcasting would seem to depend on its universality of appeal more than on anything else. Commercial broadcasting, that is, hours of broadcasting which are paid for by large commercial corporations, has in many cases arrested the wheels of progress in this field, the desire too often being merely to interest the largest number of listeners by means of performances of the most popular and obvious types of music, in presentations often undignified and boisterous. But this would seem to be but a passing phase, and the more enlightened broadcasters of this class have long since begun to recognize the value of good music in their appeals to the unseen public.

Attempts have been made to broadcast recitals of organ music, as well as performances on the organ in church services, many of which are regular features of Sunday radio programmes. On the whole, however, the organ does not broadcast well, owing partly to its excessive volume, which is apt to present difficulties to the operators responsible for its transmission. Fearing, consequently, that the full organ will "blast" and generally work havoc, the latter are inclined too often to adopt excessive toning-down methods which are fatal to satisfactory results so far as the hearer is concerned.

Nor is it only organ music which suffers in this way. Indeed, the situation which obtains to-day as regards the artistic sending out of music requires the attention of all serious-minded musicians and music lovers. As has been already said, while wireless itself is not new, its application for the purposes of entertainment is still in its comparatively early stages; to which it may be added that it demands specially-trained and musically-equipped operators if the best results are to be expected. Yet in point of fact comparatively few of the earlier operators, whose standard of culture generally speaking hardly surpassed that of telegraphists, were so equipped, nor are they to-day, many of them possessing no knowledge of music at all. Hence the unsatisfactory character of so many of the broadcast performances, as these men do not know the compositions which they are sending out and frequently, by a simple move of the hand on their boards, destroy a musical

effect which an orchestra and conductor have perhaps spent hours of rehearsal to obtain.

The future, certainly as regards the broadcasting of concert music, or music that is of better quality than the popular music of the day, will call for operators schooled in musical literature, and sensitive to the effects which conductors, instrumentalists and vocalists are striving to achieve. The question is indeed whether the existing operators are to become musicians or whether those already musically trained should be chosen as operators; and there can hardly be any doubt as to the course which should be adopted. Hence it is probable that all radio stations of the future will be manned by musically-educated operators who will be capable of dealing in an efficient and artistic manner with the musical performances which they are called on to send out.

There has been considerable speculation as to what the tastes of the radio audience really are. Arguments have been advanced contending that as a large percentage of this audience is unfamiliar with concert music, the projecting of programmes of this kind of music on the air cannot satisfy the general taste. There would seem, however, to be another side to this. In the drama and in all departments of the stage, whether light opera, grand opera, or musical comedy, there have always been those who believe in giving the public the obvious, and frequently, the meretricious, classifying this procedure under the head of giving the public "what it wants." A consideration of the history of the stage offers convincing proof, however, that in the long run this is not always the soundest or even the most profitable policy. On the contrary, managers of the more far-sighted class have constantly produced works with limited appeal but definite artistic substance, which in time have become classics and whose original unpopularity has seemed incomprehensible to later generations. And, beyond question, this is the policy which will always commend itself to the idealist and to the director with vision, as opposed to the one who desires immediate success, universal approval and quick commercial profits.

Radio broadcasting in the United States of America will unquestionably be obliged to make the choice between these conflicting policies.

(A. W. Kr.)

**BROADSIDE**, sometimes termed **BROADSHEET**, a single sheet of paper containing printed matter on one side only. The broadside seems to have been employed from the beginning of printing for royal proclamations, papal indulgences and similar documents. England appears to have been its chief home, where it was used chiefly for ballads but also as a means of political agitation and for personal statements of all kinds, especially for the dissemination of the dying speeches and confessions of criminals. It is prominent in the history of literature because several important poems, by Dryden, Butler and others, originally appeared printed on the "broad side" of a sheet. The term is also used of the simultaneous discharge of the guns on one side of a ship of war.

**In Advertising**.—In advertising, "broadside" means a single sheet of paper with an advertising message printed either on one side or on both sides that is distributed by mail or otherwise by an advertiser to customers or prospective customers. These sheets, often as large as 25in. by 38in., are folded down to a size practicable for mailing purposes, generally not larger than 5 by 10 inches. When distributed by mail, the broadside is sometimes enclosed in an envelope; on other occasions it is sent without an envelope, the address being placed on the broadside itself, which commonly is prevented from unfolding by such devices as a paster, the postage stamp or a clip. As the reader unfolds the broadside, each area disclosed by this unfolding usually bears an advertising message or other printing. The chief characteristic of the broadside is its impressive size when fully opened, a fact which permits the advertiser to secure marked emphasis through the employment of big type, and large headlines and illustrations. Some broadsides are issued with the intention of having the merchants to whom they are sent display them in their windows.

**BROADSTAIRS**, a watering-place in the Isle of Thanet (Kent), England, 3m. S.E. of Margate, on the Southern railway. Pop. of urban district, Broadstairs and St. Peter's (1921) 15,471; a high figure because census was in tourist season. Pop. (1931)

12,748. From 1837 to 1851 Broadstairs was a favourite summer resort of Charles Dickens, who, in a sketch called "Our English Watering-Place," described it as a place "left high and dry by the tide of years." This seaside village, with its "semicircular sweep of houses," grew into a considerable town owing to the influx of summer visitors. Dickens' residence was called Fort House, but it became known as Bleak House, through association with his novel of that name, written after his last visit to Broadstairs in 1851. Broadstairs has a small pier for fishing-boats, first built in the reign of Henry VIII. Not far off is the site of a chapel of the Virgin, to which ships were accustomed to lower their top-sails as they passed. Kingsgate, on the North Foreland, north of Broadstairs on the coast, changed its name from St. Bartholomew's Gate in honour of Charles II.'s landing here with the duke of York in 1683 on his way from London to Dover.

**BROADSWORD**, a sword with a broad blade, used normally for delivering a cut rather than a thrust. (See CLAYMORE.)

**BROADWAY**, the main street of New York city (see NEW YORK CITY).

**BROCA, PAUL** (1824-1880), French surgeon and anthropologist, was born at Sainte-Foy la Grande, Gironde, June 28, 1824. After completing his medical studies in Paris, he rose rapidly in his profession; in 1867 he became a member of the Academy of Medicine and professor of surgical pathology to the Faculty. He published treatises on cancer, aneurism, etc., and in 1861 announced his discovery of the seat of articulate speech in the left side of the frontal region of the brain, since known as the convolution of Broca. To him is due the formula that a full-grown man

FIG. 1.—SICULO-SARACENIC BROCADE OF THE 11TH OR 12TH CENTURY. Five and one-half inches square, this brocade is woven in red and olive green silks and gold thread on a cream-coloured ground. Along the top is the Kufic inscription, "Ar-rahman" (The Merciful), several times repeated.

should weigh as many kilogrammes as he measures centimetres in height over one metre. But his name is associated most closely with the modern school of anthropology. Establishing the Anthropological Society of Paris in 1859, of which he was secretary till his death, he was practically the inventor of the modern science of craniology. He founded *La Revue d'Anthropologie* in 1872, and it was in its pages that the larger portion of his writings appeared. Later Broca turned to the exclusive study of the brain, in which his greatest triumphs were achieved (see APHASIA). He died July 9, 1880. He received his Legion of Honour in 1868 and was honorary fellow of learned societies throughout the world.

**BROCADE**, the name usually given to a class of decorative textiles enriched on their surface with weavings in low relief, of which the floating threads at the back hang loose or are cut away.

The Latin word *broccus* is related equally to the Italian *brocato*, the Spanish *brocar* and the French *brocarts* and *brocher*, and implies a form of stitching or broaching, so that textile fabrics woven with an appearance of added stitching or broaching have consequently come to be termed "brocades." A Spanish document dated 1375 distinguishes between *los draps d'or é d'argent o de seda and brocats d'or é d'argent*, a difference which is perceived when, for instance, the make of cloths of gold, Indian kincobs,

of Persia, Syria and parts of southern Europe and northern Africa; and the 11th or 12th century Siculo-Saracenic specimen in fig. 1, is an example in which the heads of the pairs of animals and birds are broached with gold thread. Of typically Mohammedan design finely displayed, is the sumptuous Siculo-Saracenic brocade of coloured silks and gold threads from the

FIG. 3.—NORTH ITALIAN BROCADE OF THE 14TH CENTURY, 11 IN. SQUARE. This is a piece of blue satin brocaded with gold threads. The bird shapes are remotely related to, if not derived from, the Chinese mystical "feng-hoang" (鳳凰).

famous Hotel des Tiraz in Palermo made into an official robe of Henry IV. (1165-97) as emperor of the Holy Roman empire, and now in the cathedral of Regensburg (fig. 2); it is a variety of brocade design of 12th or 13th century Rhenish-Byzantine manufacture. Spanish weavers, contemporarily working at Almeria, Malaga, Grenada and Seville used corresponding designs. In the 14th century the making of satins heavily brocaded with gold threads was associated conspicuously with such Italian towns as Lucca, Genoa, Venice and Florence. Fig. 3 is from a piece of

14th century dark-blue satin broched in relief with gold thread in a design similar to that in the background of Orcagna's "Coronation of the Virgin," now in the National Gallery, London. Dur-

FIG. 5.—FRENCH BROCADE OF 3RD QUARTER OF THE 18TH CENTURY

This silk brocade is woven on a pale blue ribbed ground, with a pattern of roses and other flowers 45 in. by 19½ inches

design, in which the brocading is done with coloured silks only. During the 18th century Spitalfields competed with Lyons in manufacturing many sorts of brocades, specified in a collection of designs preserved in the art library of the Victoria and Albert

museum in London, as "brocade lustring, brocade tabby, brocade tissue, brocade damask, brocade satin, Venetian brocade, and India figured brocade." Brocading in China seems to be of considerable antiquity, and Dr. Bushell in his valuable handbook on Chinese art cites a notice of five rolls of brocade with dragons woven upon a crimson ground, presented by the emperor Ming Ti of the Wei dynasty, in the year A.D. 238, to the reigning empress of Japan; and varieties of brocade patterns are recorded as being in use during the Sung dynasty (960-1279). The first edition of an illustrated work upon tillage and weaving was published in China in 1210, and contains an engraving of a loom constructed to weave flowered-silk brocades such as are woven at the present time at Suchow, Hangchow and elsewhere. Although described usually as brocades, certain specimens of imperial Chinese robes sumptuous in ornament, sheen and the glisten of golden threads, are woven in the tapestry-weaving manner and without brocading.

**BROCADE OF COTTON.** The word brocade is employed as a conventional trade term to describe a wide range especially of cotton fabrics of simple structure and consisting of one series each of warp and weft threads, as distinct from compound structures with two or more of each series of those threads. Originally, however, the term "brocade" applied more particularly to fabrics produced from silk and sometimes richly embellished with figuring of gold and silver threads that were "broched," "pricked" or "stitched" into the woven fabric in order to develop a raised or embossed pattern, in the style of embroidery. (See BROCADE.)

The type of fabrics generally described as "cotton brocades," as produced by modern powerlooms (of which a typical model

BY COURTESY OF MESSRS. HACKING AND COMPANY, LTD.

FIG. 1.—LANCASHIRE MODERN POWER LOOM, EQUIPPED WITH DOUBLE-ACTING JACQUARD MACHINE AND FIGURING HARNESS FOR COTTON BROCADE FABRICS

is illustrated in fig. 1), are embellished with Jacquard figuring developed by causing either warp, weft, or both series of threads to "float," or lie more or less freely, in the figure portions of the

design, usually on a neutral ground texture of the plain calico or "tabby" weave, or other suitable weave structure, in order to develop an effect in contrast with that of the figuring.

Cotton brocades constitute one of the largest classes of woven fabrics that are employed for an infinite variety of domestic

FIG. 2.—COTTON BROCADE WITH ALL-WEFT FIGURING ON A NEUTRAL GROUND TEXTURE OF THE CALICO WEAVE

purposes, as, for example, bed counterpanes, hangings, curtains, table covers, and similar household articles; whilst those of lighter texture are used as ladies' and children's dress fabrics.

Cotton brocade fabrics may be broadly classified under the following chief modifications, viz.:

1. With all-weft figuring on a neutral ground texture of the calico weave, as in the example illustrated in fig. 2.
2. With all-warp figuring on a neutral ground texture.
3. With all-weft figuring on an all-warp ground texture, as in the example illustrated in fig. 3.
4. With all-warp figuring on an all-weft ground texture.
5. With warp and weft figuring on a neutral ground texture.
6. With warp and weft figuring on a diapered ground texture, as in the example illustrated in fig. 4.

**Reversible Fabrics.**—In addition to these chief modifications, the brocade principle of weaving permits of endless combinations of the above-named variations. It will be apparent, therefore, that brocade textures are virtually reversible in respect of the general design, but not in respect of colour where warp and weft threads are of different colour.

Brocade fabrics are made either one-sided or reversible, according to the particular purpose for which they are intended. If they are not reversible they are usually produced with warp and weft of widely different counts and quality, and also with a greater number of threads per inch in one direction than in the other. For the purpose of hangings and curtains in which both sides of the fabric are exposed to view, the disparity in the counts, quality, and the relative amount of warp and weft, may be less pronounced than for dress materials and furnishing fabrics, of which one side only will be exposed to view, when in use.

See H. Nisbet, *Grammar of Textile Design* (1927).

**BROCCHI, GIOVANNI BATTISTA** (1772–1826), Italian mineralogist and geologist, was born at Bassano. His treatise on the iron mines of Mella, *Trattato mineralogico e chimico sulle miniere di ferro del dipartimento del Mella* (1808), procured him the office of inspector of mines in the recently established kingdom of Italy. His most important work is the *Conchiologia fossile subapennina con osservazioni geologiche sugli Apennini, e sul suolo adiacente* (Milan, 1814), containing accurate details of the structure of the Apennine range, and an account of the fossils of the Italian Tertiary strata compared with existing species. In his *Dello stato fisico del suolo di Roma* (1820) he corrected the erroneous views of Breislak, who conceived that Rome occupies the site of a volcano, to which he ascribed the volcanic materials that cover the seven hills. Brocchi died at Khartum while on a geological expedition to the Sudan.

**BROCCOLI**, a large green vegetable resembling the cauliflower in appearance, and the cabbage in flavour. Botanically it is a variety of cabbage (*Brassica oleracea* Var. *italica*). The centre containing the curds of buds is less compact than that of the cauliflower and the leaves are smaller than those of the cabbage. Broccoli is used extensively in Italian cookery. If boiled and then allowed to simmer in olive-oil to which garlic has been added, it is especially delicious.

**BROCHANTITE**, a mineral species consisting of a basic copper sulphate ( $\text{Cu}_2[\text{OH}]_2\text{SO}_4$ ), crystallizing in the orthorhombic system. The crystals are usually small and are prismatic or acicular in habit; they have a perfect cleavage in one direction. They are transparent to translucent, with a vitreous lustre; and are of an emerald-green to blackish-green colour. Specific gravity 3.907; hardness  $3\frac{1}{2}$ –4. The mineral has been found associated with malachite, etc., in copper mines at several places. A microscopical examination of the green copper ores of secondary origin in the Clifton and Morenci district of Arizona proves brochantite to be of extremely common occurrence mostly intergrown with malachite, which effectually masks its presence. (L. J. S.)

**BROCK, SIR ISAAC** (1769–1812), British soldier and administrator, was born at St. Peter Port, Guernsey, on Oct. 6, 1769. Joining the army at the age of 15 as an ensign of the 8th regiment, he became a lieutenant-colonel in 1797, after less than 13 years' service. From 1802 to 1805 he was with his regiment in Canada, returning thither in 1806 in view of the imminence of war between Great Britain and the United States. From Sept. 1806 till Aug. 1810 he was in charge of the garrison at Quebec; in the latter year he assumed the command of the troops in Upper Canada, and then took over the civil administration of that province as provisional lieutenant-governor. On the outbreak of the war of 1812 Brock had to defend Upper Canada against invasion by the United States. In the face of many difficulties and not a little disaffection, he organized the militia of the province, drove back the invaders, and on Aug. 16 1812, with about 730 men and 600 Indians commanded by their chief Tecumseh, compelled the American force of 2,500 men under General William Hull (1753–1825) to surrender at Detroit, an achievement which gained him a knighthood of the Bath and the popular title of "the hero of Upper Canada." From Detroit he hurried to the Niagara frontier, but on Oct. 13 was killed at the battle of Queenston Heights.

His *Life and Correspondence* by his nephew, Ferdinand Brock Tupper (2nd ed., 1847), still remains the best; later lives are by D. R. Read (Toronto, 1894), and by Lady Edgar (1905).

**BROCK, SIR THOMAS** (1847–1922), English sculptor, was the chief pupil of Foley, and later became influenced by the new romantic movement. His group "The Moment of Peril" was followed by "The Genius of Poetry," "Eve," and other ideal works that mark his development. His busts, such as those of Lord Leighton and Queen Victoria; his statues, such as "Sir Richard Owen" and "Dr. Philpott, bishop of Worcester"; his sepulchral monuments, such as that to Lord Leighton in St. Paul's cathedral, a work of singular significance, refinement, and beauty; and his memorial statues of Queen Victoria, at Hove and elsewhere, are examples of his power as a portraitist, sympathetic in feeling, sound and restrained in execution, and dignified and decorative in arrangement. The colossal equestrian statue of "Edward

the Black Prince" was set up in the City Square in Leeds in 1901, the year in which the sculptor was awarded the commission to execute the vast Imperial Memorial to Queen Victoria in front of Buckingham Palace. Brock was elected an associate of the Royal Academy in 1883 and full member in 1891. Among his later works were: busts of King Edward VII. (1911), Lord Lister (1913, for the Royal College of Surgeons, London) and Edwin Abbey, R.A. (1917, for the British School in Rome); statues of Captain Cook (1914, in the Mall, London) and of Lord Sydenham (1915, in Bombay). In 1911 he was created K.C.B. He died in London Aug. 22, 1922.

**BROCKDORFF-RANTZAU, ULRICH**, COUNT VON (1869-1928), German diplomatist, was born in Slesvig Nord, May 29 1869. He entered the diplomatic service in 1894. From 1909 to 1912 he was consul-general at Budapest, and from 1912 to 1918 German minister at Copenhagen. On Dec. 20 1918, he was appointed secretary of State for foreign affairs, in which capacity he led the German delegation at the Peace Conference at Versailles in April 1919. Unwilling to advise the German Government to accept the terms of the Treaty of Versailles, he resigned on June 20. In 1922 he was appointed German ambassador in Moscow. He died while on leave in Berlin on Sept. 8, 1928.

**BROCKEN**, a mountain of Germany, in Prussian Saxony, the highest point (3,733ft.) of the Harz, and indeed of north Germany. Its huge, granite-strewn dome commands magnificent views in all directions; to Magdeburg and the Elbe, Leipzig and the Thuringian forest. A mountain railway (12m.) gives access to the summit. In the folk-lore of north Germany the Brocken holds an important place, and long after the introduction of Christianity traditional rites continued to be enacted here annually on Walpurgis night (May 1). In literature it is represented in the famous "Brocken scene" in Goethe's *Faust*.

**BROCKEN, SPECTRE OF THE** (so named from having been first observed in 1780 on the Brocken), an enormously magnified shadow of an observer cast upon a bank of cloud in high mountain regions when the sun is low. The shadow, often accompanied by coloured bands, reproduces every motion of the observer in the form of a gigantic but misty image of himself.

**BROCKES, BARTHOLD HEINRICH** (1680-1747), German poet, was born at Hamburg on Sept. 22, 1680. He studied jurisprudence at Halle, and after extensive travels in Italy, France and Holland, settled in his native town in 1704. In 1720 he was appointed a member of the Hamburg senate, and entrusted with several important offices. Six years (from 1735 to 1741) he spent as *Amtmann* (magistrate) at Ritzebüttel. He died in Hamburg Jan. 16, 1747. Brockes's poetic works were published in a series of nine volumes under the fantastic title *Irdisches Vergnügen in Gott* (1721-48); he also translated Marini's *La Strage degli innocenti* (1715), Pope's *Essay on Man* (1740), and Thomson's *Seasons* (1745). He was one of the first German poets to substitute for the bombastic imitations of Marini, to which he himself had begun by contributing, a clear and simple diction. His verses, artificial and crude as they often are, express a reverential attitude towards nature and a religious interpretation of natural phenomena which was new to German poetry.

Brockes' autobiography was published by J. M. Lappenberg in the *Zeitschrift des Vereins für Hamburger Geschichte*, ii. (1847). See also A. Brandl, *B. H. Brockes* (1878), and D. F. Strauss, *Brockes und H. S. Reimarus (Gesammelte Schriften, ii.)*.

**BROCKET**, the name given to a yearling stag of the red deer (*q.v.*), and hence to several South American deer whose simple horns resemble those of a stag a year old.

**BROCKHAUS, FRIEDRICH ARNOLD** (1772-1823), German publisher, was born at Dortmund, on May 4, 1772. He devoted two years at Leipzig to the study of modern languages and literature, after which he set up an emporium for English goods. In 1805 he began business as a publisher. About 1808 Brockhaus purchased the copyright of the *Konversations-Lexikon*, which was started in 1796, and in 1810-11 he completed the first edition of this encyclopaedia (17th ed. 1908-10; new impression 1920); a second edition under his own editorship was

begun in 1812. His business extended rapidly, and in 1818 Brockhaus removed to Leipzig, where he established a large printing-house. Among the more extensive of his many literary undertakings were the critical periodicals—*Hermes*, the *Literarisches Konversationsblatt* (afterwards the *Blätter für literarische Unterhaltung*), and the *Zeitgenossen*, and some large historical and bibliographical works, such as Raumer's *Geschichte der Hohenstaufen*, and Ebert's *Allgemeines bibliographisches Lexikon*. F. A. Brockhaus died at Leipzig on Aug. 20, 1823. The business was carried on by his sons, Friedrich (1800-65), who retired in 1850, and Heinrich (1804-74), under whom it was considerably extended. In the years 1842-48, Heinrich Brockhaus represented Leipzig in the Saxon second chamber, was made honorary citizen of that city in 1872, and died there on Nov. 15, 1874. He was succeeded by his sons Eduard (1820-1914), and Rudolf (1838-98). Eduard was a member of the Reichstag (1871-78), and one of the accepted leaders of the book trade in Germany. The business was continued by members of the family.

See H. E. Brockhaus, *Friedrich A. Brockhaus, sein Leben und Wirken nach Briefen und andern Aufzeichnungen* (Leipzig, 1872-81), and *Die Firma F. A. Brockhaus von der Begründung bis zum hundertjährigen Jubiläum 1805-1905* (Leipzig, 1905).

Another of Friedrich's sons, **HERMANN BROCKHAUS** (1806-1877), German Orientalist, was born at Amsterdam on Jan. 28, 1806. He was appointed extraordinary professor in Jena in 1838, and in 1841 at Leipzig, where in 1848 he was made ordinary professor of ancient Semitic. He died at Leipzig on Jan. 5, 1877. His most important work was the *editio princeps* (1839) of the *Kathā-sarit-sāgara*, "The Ocean of the Streams of Story," the large collection of Sanskrit stories made by Soma Deva in the 12th century.

**BROCKLESBY, RICHARD** (1722-1797), English physician, was born at Minehead, Somersetshire, on Aug. 11, 1722. He was educated at Ballitore, in Ireland, where Edmund Burke was one of his schoolfellows, studied medicine at Edinburgh, and finally graduated at Leiden in 1745. Appointed physician to the army in 1758, he served in Germany during part of the Seven Years' War, and on his return settled down to practise in London. In 1764 he published *Economical and Medical Observations*, which contained suggestions for improving the hygiene of army hospitals. He was warmly attached to Dr. Johnson, to whom about 1784 he offered an annuity of £100 for life, and whom he attended on his death-bed, while in 1788 he presented Burke with £1,000, and offered to repeat the gift "every year until your merit is rewarded as it ought to be at court." He died on Dec. 11, 1797, leaving his house and part of his fortune to his grand-nephew, Dr. Thomas Young.

**BROCKTON**, a city of Plymouth county (Mass.), United States, about 20m. S. of Boston; served by the New York, New Haven and Hartford railroad. Its area is 21.4 sq. miles. Its population in 1920 was 66,254, of whom 17,124 were foreign-born whites, and in 1930, Federal census, was 63,797.

The manufacture of men's shoes has long been the dominating industry. In 1927 there were 60 shoe factories, with a yearly output valued at \$100,000,000; four last factories, making over 1,000,000 pairs of lasts annually; and numerous other industries producing articles used by the shoe manufacturers, such as patterns, trimmings, rands, blackings and stains (for which the water supply is especially suited), machinery and tools. Brockton is the trading centre for a large population, and is headquarters of the county farm bureau. An annual fair, with an attendance in recent years of over 215,000, has been held since 1873, to promote the agricultural, industrial and educational interests of the city and the county. No dividends are paid, the directors serve without salary, and the profits are used for such purposes as providing scholarships for boys and girls of the county.

The savings banks of the city in 1926 carried 51,058 accounts, with deposits aggregating \$20,772,741. The assessed valuation of property was \$72,610,050. The city spends annually nearly \$1,000,000 on public schools and libraries, and nearly \$300,000 on sanitation and the conservation of health. For three successive years it won the state award for the best milk supply in

Massachusetts. Its death rate is exceptionally low for an industrial city.

Brockton was a part of Bridgewater until 1821, when it was incorporated as the town of North Bridgewater. Its present name was adopted in 1874, and the city was chartered in 1881. The population was 8,007 in 1870; 13,608 in 1880; 27,294 in 1890; 40,063 in 1900; and 56,878 in 1910. It was the first city in Massachusetts to abolish all grade crossings (1896); and was a pioneer in using electricity for lighting the streets and operating the street railway system.

**BROCKVILLE**, port of entry, Ontario, Canada, capital of Leeds county, named after General Sir Isaac Brock, situated 110m. S.W. of Montreal, on the left bank of the St. Lawrence, and Canadian National railway, with a branch to the Canadian Pacific. Steamers go to St. Lawrence and Lake Ontario ports, and it is a summer resort. Hardware, furnaces, agricultural implements, automobiles, motor boats and chemicals are made. It is an important dairy-centre, and ships large quantities of cheese and butter. Pop. (1931) 9,736.

**BROD, MAX** (1884– ), German writer, was born in Prague on May 27, 1884 of Jewish parents. He received his education in Prague, and afterwards worked there, first as a Government official, and later on the staff of the *Prager Tagblatt*. Brod's work is strongly steeped in that peculiar compound of the Jewish, Czech and German national spirits which makes the German literature of Prague a thing apart—fantastic, mystic, with flashes of violent realism, strongly erotic, intellectually acute and abnormally sensitive to atmosphere. Brod's own work is further characterized by exceptional narrative skill and limpidity of style. His chief works are: *Schloss Nornepygge* (1908), *Jüdinnen* (1909), *Weberwirtschaft* (1913), *Tycho Brahes Weg zu Gott* (1916; English tr. *Tycho Brahe's Redemption*, 1928), *Reubeni* (1925), *Die Frau, nach der man sich sehnt* (1927).

**BROD**, a rural town of Yugoslavia, on the left bank of the river Sava. Pop. (1921) 10,621. The railway from Zagreb to Belgrade crosses the river here; and Brod is the junction for the principal Bosnian line, to Sarajevo, Mostar and the Adriatic. Its slight economic value will be increased when the tunnelling which is to replace the funicular section has been completed. Brod has a considerable transit trade in cereals, wines, spirits, prunes and wood. Its chief industries are plum-growing and pig-rearing. It has also a distillery and Government showrooms for agricultural implements. It is sometimes called Slavonisch-Brod to distinguish it from Bosnisch-Brod across the river. The town owes its name to a ford (Serbian *brod*) of the Sava, and dates at least from the 15th century. Brod was frequently captured and recaptured in the wars between Turkey and Austria; and it was here that the Austrian army mustered in 1870 for the occupation of Bosnia.

**BRODERIP, WILLIAM JOHN** (1789–1859), English naturalist, was born in Bristol and became a metropolitan police magistrate, first at the Thames police court and then at Westminster. He was one of the founders of the Zoological Society of London, and his collection of shells was ultimately bought by the British Museum. His works are *Zoological Recreations* (1848) and *Leaves from the Note-book of a Naturalist* (1852).

**BRODIE, SIR BENJAMIN COLLINS, 1ST BART.** (1783–1862), English physiologist and surgeon, was born in 1783 at Winterslow, Wiltshire. He was assistant surgeon at St. George's hospital for over 30 years. In 1810 he was elected a fellow of the Royal Society. Probably his most important work is *Pathological and Surgical Observations on the Diseases of the Joints*, in which he attempts to trace the beginnings of disease in the different tissues that form a joint, and to give an exact value to the symptom of pain as evidence of organic disease. This volume led to the adoption by surgeons of measures of a conservative nature in the treatment of diseases of the joints, with consequent reduction in the number of amputations and the saving of many limbs and lives. In 1854 he published anonymously a volume of *Psychological Inquiries*; to a second volume which appeared in 1862 his name was attached. He received many honours during his career, was created a baronet in 1834, and was the first president of the General Medical Council. He died at Broome Park,

Surrey, Oct. 21, 1862. His collected works, with autobiography, were published in 1865 under the editorship of Charles Hawkins.

His eldest son, **SIR BENJAMIN COLLINS BRODIE, 2ND BART.** (1817–80), was appointed professor of chemistry at Oxford in 1865, and is chiefly known for his investigations on the allotropic states of carbon and for his discovery of graphitic acid.

**BRODIE, PETER BELLINGER** (1815–1897), English geologist, was born in London, and studied at Emmanuel college, Cambridge, where he came under the spell of Sedgwick. Entering the church in 1838, he held various preferments, but all his leisure time was devoted to geology. In the Vale of Wardour he discovered in Purbeck Beds the isopod named by Milne-Edwards *Archaeoniscus Brodiei*. Fossil insects formed the subject of his special studies (*History of the Fossil Insects of the Secondary Rocks of England*, 1845), and many of his published papers relate to them.

See Memoir by H. B. Woodward in *Geological Magazine*, 1897.

**BROEKHUIZEN, JAN VAN** (JANUS BROUKHUSIUS), (1649–1707), Dutch classical scholar and poet, was born at Amsterdam. He entered the army, and in 1674 was sent with his regiment to America, in the fleet under Admiral de Ruyter, but returned to Holland the same year. In 1678 he was sent to the garrison at Utrecht, where he became the friend of Graevius. Later he became a captain of one of the companies then at Amsterdam. After the Peace of Ryswick, 1697, his company was disbanded and he retired on a pension.

His Dutch poems, in which he followed the model of Pieter Hooft, were first published in 1677; a later edition, with a biography by D. van Hoogstraten, appeared in 1712; the last edition, 1883, was edited by R. A. Kollwijn. His classical reputation rests on his editions of Propertius (1702) and Tibullus (1707). His Latin poems (*Carmina*) appeared in 1684; a later edition (*Poemata*) by D. van Hoogstraten appeared in 1711. The *Select Letters* (*Jani Broekhusii Epistolae Selectae*, 1889 and 1893) were edited by J. A. Worp, who also wrote his biography (1891).

**BROENDSTED, PETER OLUF** (1780–1842), Danish archaeologist and traveller, was born at Fruering in Jutland. After a visit to Italy, he spent three years (1810–13) in research and excavation in Greece; later (1820–21), while envoy at the papal court, he visited Sicily and the Ionian Islands for the same purpose. In 1832 he returned to Copenhagen as director of the museum; he was made rector in 1842 and died in the same year. His principal work was the *Travels and Archaeological Researches in Greece* (in German and French, 1826–30), of which only two volumes were published, dealing with the island of Ceos and the metopes of the Parthenon. A volume of his letters (*Memoirer og Breve*) was published at Copenhagen in 1926.

**BROGGER, WALDEMAR CHRISTOFER** (1851– ), Norwegian geologist, born in Christiania (Oslo) on Nov. 10, 1851, and educated in that city. He was professor of mineralogy and geology from 1881 to 1890 in the university of Stockholm, and from 1890 in the university of Christiania, of which he later became Rector. His observations on the igneous rocks of south Tirol compared with those of Christiania afford much information on the relations of the granitic and basic rocks. The subject of the differentiation of rock-types in the process of solidification as plutonic or volcanic rocks from a particular magma received much attention from him. He dealt also with the Palaeozoic rocks of Norway, and with the late glacial and post-glacial changes of level in the Christiania region.

**BROGLIE, DE**, the name of a noble French family which, originally Piedmontese, emigrated to France in the year 1643. The head of the family, **FRANÇOIS MARIE** (1611–56), then took the title of comte de Broglie. He had already distinguished himself as a soldier, and died, as a lieutenant-general, at the siege of Valenza on July 2, 1656. His son, **VICTOR MAURICE, COMTE DE BROGLIE** (1647–1727), served under Condé, Turenne and other great commanders of the age of Louis XIV., becoming *maréchal de camp* in 1676, lieutenant-general in 1688, and finally marshal of France in 1724.

The eldest son of Victor Maurice, **FRANÇOIS MARIE**, afterwards **DUC DE BROGLIE** (1671–1745), served continuously in the War of

the Spanish Succession and was present at Malplaquet. The war in Italy called him into the field again in 1733, and in the following year he was made marshal of France. In the campaign of 1734 he fought the battles of Parma and Guastalla. A famous episode was his narrow personal escape when his quarters on the Secchia were raided by the enemy on the night of Sept. 14, 1734. In 1735 he directed a war of positions with credit, but he was soon replaced by Marshal de Noailles. He was governor-general of Alsace when Frederick the Great paid a secret visit to Strasbourg (1740). In 1742 de Broglie was appointed to command the French army in Germany, but such powers as he had possessed were failing him, and he had always been the "man of small means," safe and cautious, but lacking in elasticity and daring. The only success obtained was in the action of Sahay (May 25, 1742), for which he was made a duke.

His son, VICTOR FRANÇOIS, DUC DE BROGLIE (1718-1804), served with his father at Parma and Guastalla, and in 1734 obtained a colonelcy. In the German War he took part in the storming of Prague in 1742, and was made a brigadier. In 1744 and 1745 he saw further service on the Rhine, and in 1756 he was made *maréchal de camp*. He subsequently served with Marshal Saxe in the low countries, and was present at Roucoux, Val and Maastricht. At the end of the war he was made a lieutenant-general. During the Seven Years' War he served successively under d'Estrées, Soubise and Contades, being present at all the battles from Hastenbeck onwards. His victory over Prince Ferdinand at Bergen (1759) won him the rank of marshal of France from his own sovereign and that of prince of the empire from the emperor Francis I. In 1760 he won an action at Corbach, but was defeated at Vellinghausen in 1761. After the war he was in disgrace until 1778, when he was given command of the troops designed to operate against England. He opposed the Revolution with determination, and after his emigration, commanded the "army of the princes" for a short time (1792). He died at Münster in 1804.

Another son of the first duke, CHARLES FRANÇOIS, COMTE DE BROGLIE (1719-1781), is chiefly remembered in connection with the *Secret du Roi*, the private, as distinct from the official, diplomatic service of Louis XV. of which he was the ablest and most important member.

The son of Victor François, VICTOR CLAUDE, PRINCE DE BROGLIE (1757-1794), served in the army, attaining the rank of *maréchal de camp*. He served with Lafayette and Rochambeau in America, was a member of the Jacobin Club, and sat in the Constituent Assembly, constantly voting on the Liberal side. He served as chief of the staff to the Republican army on the Rhine; but in the Terror he was denounced, arrested and executed at Paris on June 27, 1794. His dying admonition to his little son was to remain faithful to the principles of the Revolution, however unjust and ungrateful.

ACHILLE CHARLES LÉONCE VICTOR, DUC DE BROGLIE (1785-1870), statesman and diplomatist, son of the last-named, was born in Paris on Nov. 28, 1785, and died in Paris, Jan. 25, 1870. In 1809, he was added to the Council of State, over which Napoleon presided in person; and was sent by the emperor on diplomatic missions, as attaché, to various countries. He received, in June, 1814, a summons from Louis XVIII. to the Chamber of Peers. There, after the Hundred Days, he distinguished himself by his courageous defence of Marshal Ney, for whose acquittal he, alone of all the peers, both spoke and voted. On Feb. 15, 1816, he was married at Leghorn to the daughter of Madame de Staël. He returned to Paris at the end of the year, but took no part in politics until the elections of Sept. 1817 broke the power of the "ultra-royalists" and substituted for the *Chambre introuvable* a moderate assembly. During the last critical years of Charles X.'s reign, de Broglie identified himself with the *doctrinaires*, among whom Royer-Collard and Guizot were the most prominent. After the July revolution he was minister of education for a few months. After the insurrection of June 1832, de Broglie took office once more as minister for foreign affairs (Oct. 11). His tenure of the foreign office was coincident with a very critical period in international relations. But for the sympathy of Great Britain under

Palmerston, the July monarchy would have been completely isolated in Europe; and this sympathy the aggressive policy of France in Belgium and on the Mediterranean coast of Africa had been in danger of alienating. The Belgian crisis had been settled, so far as the two powers were concerned, before de Broglie took office; but the concerted military and naval action for the coercion of the Dutch, which led to the French occupation of Antwerp, was carried out under his auspices. The good understanding of which this was the symbol characterized also the relations of de Broglie and Palmerston during the crisis of the first war of Mehmet Ali (*q.v.*) with the Porte, and in the affairs of the Spanish peninsula their common sympathy with constitutional liberty led to the treaty of alliance between Great Britain, France, Spain and Portugal, signed at London on April 22, 1834. De Broglie had retired from office in the February preceding, and did not return to power till March of the following year, when he became head of the cabinet. In 1836, on the defeat of the government, he once more resigned, and never returned to official life. He had found France isolated and Europe full of the rumours of war; he left her strong in the English alliance and the respect of Liberal Europe, and Europe freed from the restless apprehensions which were to be stirred into life again by the attitude of Thiers in the Eastern Question and of Guizot in the affair of the "Spanish marriages." From 1836 to 1848 de Broglie held almost completely aloof from politics. The revolution of 1848 was a great blow to him. He took his seat, however, in the republican National Assembly and in the Convention of 1848, and, as a member of the section known as the "Burgraves," did his best to stem the tide of socialism and to avert the reaction in favour of autocracy which he foresaw. He shared with his colleagues the indignity of the *coup d'état* of Dec. 2, 1851, and remained for the remainder of his life one of the bitterest enemies of the imperial régime, though he was heard to remark, with that caustic wit for which he was famous, that the empire was "the government which the poorer classes in France desired and the rich deserved." The last twenty years of his life were devoted chiefly to philosophical and literary pursuits.

Besides his *Souvenirs*, in 4 vols. (1885-88), the duc de Broglie's published works include *Écrits et discours* (3 vols., 1863); *Le Livre Échange et l'impôt* (1879); *Vues sur le gouvernement de la France* (1861). This last was confiscated before publication by the imperial government. See Guizot, *Le Duc de Broglie* (1870), and *Mémoires* (1858-67); and the histories of Thureau-Dangin and Duvergier de Hauranne.

JACQUES VICTOR ALBERT, DUC DE BROGLIE (1821-1901), his eldest son, was born at Paris on June 13, 1821. After a brief diplomatic career at Madrid and Rome, the revolution of 1848 caused him to withdraw from public life. He had already published a translation of the religious system of Leibnitz (1846). His contributions to the *Revue des deux Mondes* and the Orleanist and clerical organ *Le Correspondant*, were afterwards collected under the titles of *Études morales et littéraires* (1853) and *Questions de religion et d'histoire* (1860). These were supplemented in 1869 by a volume of *Nouvelles études de littérature et de morale*. His *L'Église et l'empire romain au IV<sup>e</sup> siècle* (1856-66) brought him a seat in the Academy in 1862. In 1870 he succeeded his father in the dukedom. In the following year he was elected to the National Assembly for the department of the Eure, and a few days later (on Feb. 19) was appointed ambassador in London; but in March 1872, in consequence of criticisms upon his negotiations concerning the commercial treaties between England and France, he resigned his post and took his seat in the National Assembly, where he became the leading spirit of the monarchical campaign against Thiers. On the replacement of the latter by Marshal MacMahon, the duc de Broglie became president of the council and minister for foreign affairs (May 1873), but in the reconstruction of the ministry on Nov. 26 transferred himself to the ministry of the interior. His tenure of office was marked by an extreme conservatism, which roused the bitter hatred of the Republicans, while he alienated the Legitimist party by his friendly relations with the Bonapartists, and the Bonapartists by an attempt to effect a compromise between the rival claimants to the monarchy. The result was the fall of the cabinet.

on May 18, 1874. Three years later (May 16, 1877) he was entrusted with the formation of a new cabinet, with the object of appealing to the country and securing a new chamber more favourable to the reactionaries than its predecessor had been. The result, however, was a decisive Republican majority. The duc de Broglie was defeated in his own district, and resigned office on Nov. 20. Not being re-elected in 1885, he abandoned politics for historical work. He died in Paris on Jan. 19, 1901.

Besides editing the *Souvenirs* of his father (1886, etc.), the *Mémoires* of Talleyrand (1891, etc.) and the *Letters* of the Duchess Albertine de Broglie (1896), he published *Le Secret du roi, Correspondance secrète de Louis XV. avec ses agents diplomatiques, 1752-74* (1878); *Frédéric II. et Marie Thérèse* (1883); *Frédéric II. et Louis XV.* (1885); *Marie Thérèse Impératrice* (1888); *Le Père Lacordaire* (1889); *Maurice de Saxe et le marquis d'Argenson* (1891); *La Paix d'Aix-la-Chapelle* (1892); *L'Alliance autrichienne* (1895); *La Mission de M. de Gontaut-Biron à Berlin* (1896); *Voltaire avant et pendant la Guerre de Sept Ans* (1898); *Saint Ambroise*, translated by Margaret Maitland in the series of "The Saints" (1899).

**BROGUE.** (1) A rough shoe of raw leather (Gael. *brog*, a shoe) worn in parts of Ireland and the Scottish Highlands, and applied generally to shoes intended for country wear. (2) A dialectical accent, especially used of the Irish accent in speaking English.

**BROHAN, AUGUSTINE SUSANNE** (1807-1887), French actress, was born in Paris on Jan. 22 1807 and died on Aug. 16 1887. She made her first Paris appearance at the Odéon in 1832 as Dorine in *Tartuffe*. She appeared at the Comédie Française, Feb. 1834, as Madelon in *Les Précieuses ridicules*, and Suzanne in *Le Mariage de Figaro*, and continued to act until 1842.

Her elder daughter, JOSEPHINE FÉLICITÉ AUGUSTINE BROHAN (1824-1893), made her *début* at the Comédie Française on May 19, 1841, as Dorine in *Tartuffe*, and Lise in *Rivaux d'eux-mêmes*. She retired in 1866.

Susanne Brohan's second daughter, ÉMILIE MADELEINE BROHAN (1833-1900), made her *début* at the Comédie Française in a new comedy by Scribe and Legouvé, *Les Contes de la reine de Navarre* (Sept. 1, 1850). Her name is especially associated with *Le Monde où l'on s'ennuie*, *Par droit de conquête*, *Les Deux Veuves*, and *Le Lion amoureux*, in which, as the Marquise de Maupas, she had one of her greatest successes. She retired in 1886.

**BROKE** or **BROOKE, ARTHUR** (d. 1563), English author, wrote the first English version of the story of Romeo and Juliet. *The Tragical History of Romeus and Juliet* (1562) is a rhymed account of the story, taken, not directly from Bandello's collection of novels (1554), but from the French translation (*Histoires tragiques*) of Pierre Boaistuau or Boisteau, surnamed Launay, and François de Belleforest. Broke adds some detail to the story as told by Boisteau. As the poem contains many scenes which are not known to exist elsewhere, but which were adopted by Shakespeare in *Romeo and Juliet*, there is no reasonable doubt that it may be regarded as the main source of the play. Broke perished by shipwreck in 1563, on his way from Newhaven to join the English troops fighting on the Huguenot side in France.

See, for a close comparison of Shakespeare's play with Broke's version, the reprint of the poem edited by P. A. Daniel for the New Shakespeare Society (1875).

**BROKE, SIR PHILIP BOWES VERE, BART.** (1776-1841) was born at Broke Hall, near Ipswich, England, entered the navy in 1792, and rose rapidly in the service. In 1813 he was in command of the "Shannon," which was then cruising off Boston, watching the "Chesapeake," an American frigate of the same nominal force but heavier armament. On June 1 Broke, finding his water supply getting low, wrote to Lawrence, the commander of the "Chesapeake," asking for a meeting between the two ships, stating the "Shannon's" force, and guaranteeing that no other British ship should take part in the engagement. Before this letter could be delivered, however, the "Chesapeake," under full sail, ran out of Boston harbour, crowds of pleasure boats accompanying her to witness the engagement. As the "Chesapeake" rounded to on the "Shannon's" weather quarter, at a distance of about 50 yards, the British frigate received her with a broadside. A hundred of the "Chesapeake's" crew were struck down at once, Lawrence himself being mortally wounded. A second broadside

increased the confusion, and, her tiller-ropes being shot away, the American frigate drifted foul of the "Shannon." Broke sprang on board with some 60 of his men following him. After a brief struggle the fight was over. Within 15 minutes of the firing of the first shot, the "Chesapeake" struck her flag, but Broke himself was seriously wounded. For his services he was rewarded with a baronetcy, and subsequently was made a K.C.B. His exploit captivated the public fancy, and his popular title of "Brave Broke" gives the standard by which his action was judged. Its true significance, however, lies deeper. Broke's victory was due not so much to courage as to forethought. His wound incapacitated him for further service. He died in London on Jan. 2 1841.

**BROKEN HILL** (Willyama), a famous mining city in Yancowinna county in the central west of New South Wales, 35 m. from the South Australian border. It lies at an elevation of 1,000 ft. on the east flank of the Barrier range, some 200 m. from Spencer's gulf and 550 from the east sea-board. The region is sub-arid, hot in summer, cool (with frosts) in winter; mean annual temperatures: 78°-51° F; absolute extremes: 115.9°-28.5° F; average annual rainfall c. 10 in., but erratic—3.6-17.6; average annual evaporation: c. 7 ft. 6 in. Heavy dust-storms are frequent. The mulga, bluebush and salt-bush hills and plains, richly grassed after rains, form rather poor pastoral country where not bared by the mining settlements. The highly compressed and tilted sedimentary (pre-Cambrian) rocks (with igneous intrusions and quartz reefs) of the Barrier range had a "replacement" lode which outcropped as two connected arcs over a distance of c. 3 m. with a width varying from 200 to 3 ft. The outcrop originally appeared as a manganiferous ironstone (gossan) ridge and was first mined (1883-84) for tin, though silver and lead mines of some value had previously been worked in the area, notably at Silverton. Secondary enrichment, due partly to the arid climate, had led to ores (native silver, chlorides, etc., and further down, lead carbonates) of extraordinary richness in the upper parts. Below these the ores became lead-zinc-silver sulphides of lower but more uniform value. By 1924 workings had reached a depth of 1,800 ft.; some 35,000,000 tons of ore had been removed (1925) and a further 13,000,000 tons, with uncalculated reserves beyond, were available. The value of the total output (to end of 1925) was £127,500,000 and £28,000,000 had been paid in dividends. The maximum output was in 1913—1,750,000 tons; thereafter the average has been c. 1,250,000 tons, though 1919 and 1920 were years of strikes, low prices and very low production. Ore-treatment methods have changed along with the type of ore and the growth of technical knowledge. To-day the zinc-lead-silver sulphides are uniformly dealt with by the "flotation" (eucalyptus oil) process. Smelting and concentrating, formerly conducted on the field, were progressively transferred to Port Pirie (South Australia) on Spencer's gulf (254 m. by rail) where fuel, fluxes and transport are more readily available. The zinc residues were for long used as filling or accumulated as enormous dumps. In 1913 c. 500,000 tons of zinc concentrates yielding some 200,000 tons of zinc or  $\frac{1}{4}$  of the world's supply, were shipped abroad from Broken Hill, only 5-7,000 tons zinc were produced at Port Pirie. In 1918, after experimental work, zinc production was started on a large scale (100 tons per diem) at Risdon (Hobart, Tasmania), where water-power is available for the electrolytic process. Considerable quantities of zinc concentrates (1925: 226,500 tons) are still exported (United Kingdom, Europe and Japan) but Risdon takes increasing quantities and amongst its by-products produces sulphuric acid valuable in the manufacture of superphosphates. The lead ores are now smelted almost entirely at Port Pirie. Broken Hill is the third city of New South Wales. Its population shows the fluctuations natural to a mining centre (1914: c. 35,000; 1926: c. 24,000). It is substantially built and well equipped. The difficulty of water supply has been met by the construction of two large dams, 10 and 19 miles distant respectively, and the construction of two additional reservoirs was under consideration in 1928. Broken Hill is 335 m. by rail from Adelaide and its main economic and business relations are with South Australia. Recently the line to Sydney (703 m.) has been completed and forms a possible alternative route from Adelaide to Sydney.

**BROKEN HILL PROPRIETARY COMPANY LIMITED.** This company was formed in Aug., 1885, to develop seven mining leases at Broken Hill, New South Wales, on the now famous Barrier Range. On account of the great size of the lode it was soon found that the ordinary system of mining was inadequate, and, consequently, the "square set" system of timbering was adopted. This was, as work progressed, supplemented at a later date by the "open cut," which was applied to the whole length of the mine for about 250ft. in depth. Open stoping with filling was carried out in the hard sulphide ore.

The development of the lode was phenomenal, the width of the oxidized ore, in places, being no less than 300ft. The extraordinary variety of the ores from the mine, many of these being refractory ores, raised many unusual problems. At first, direct smelting in a reduction plant, situated at Broken Hill on the property, was adopted. Later, when silicious ores came into view, chloridizing plants as well as an amalgamating plant were installed to deal with them.

With the advent of sulphide ores the method of treatment was considerably modified and water concentration took place by tables and jigs. The flotation of zinc concentrates was successfully accomplished at this mine for the first time in the world. As time went on the process has been varied, and with the invention, by the company's officers, of differential flotation (Bradford process), separate concentrates were made of the zinc and lead contents.

**Smelting.**—The first reduction plant was constructed at Broken Hill in 1886. Additions to the plant were made, until it included 15 furnaces of 80 ton capacity each. At this time, the products of the mine were shipped to Europe as silver-lead bullion. In 1889, however, the company decided to establish its own refinery, and this was brought into being at Port Pirie in South Australia. The resultant lead was sold in the markets of England, Europe, and the East, as well as supplying the requirements of the Australian States, and nearly the whole of the silver was sold to China and India. Part of the output of zinc concentrates went for production of spelter, the balance being shipped overseas. In 1898, it was decided to close down the smelters at Broken Hill and to concentrate smelting operations at Port Pirie. In 1915, the works at Port Pirie were sold. The total amount of mineral produced at this mine, to May 1927, was:

|                  |                 |
|------------------|-----------------|
| Silver . . . . . | 183,600,000 oz. |
| Lead . . . . .   | 1,365,000 tons  |
| Zinc . . . . .   | 564,000 tons    |

**Iron and Steel Works.**—The leases of the company having developed large quantities of iron ore, the question of its utilization for the production of iron and steel was seriously considered, and after exhaustive enquiries a decision was arrived at to embark on this new enterprise. As a result of this decision, an iron and steel works was built at Newcastle, N.S.W., close to coal supplies, and about 100 m. N. of Sydney. Operations here are conducted on the most modern lines. The ore is quarried in South Australia, from the side of the mountain, hauled 35 miles, loaded by belt-conveyors into the company's own ships and conveyed to Newcastle.

The plant in 1927 comprised 224 by-product coke ovens; four blast furnaces of a total capacity of 10,000 tons per week; nine basic open hearth furnaces capable of producing 10,000 tons of steel per week, a 35in. blooming mill, 28in. rail mill, 18in., 12in. and 8in. merchant mills, and a continuous rod mill. Associated with these are a large electric power station, a steel foundry, and a direct metal foundry and large machine shop.

The production figures from the inception of the steel works to May 31, 1927, were:—

|                    |                |
|--------------------|----------------|
| Steel . . . . .    | 2,500,000 tons |
| Pig Iron . . . . . | 2,500,000 tons |

The works supply a large proportion of the railway material required by the various governments of Australia, as well as meeting the demands of engineering workshops throughout Australia. The population of the district immediately surrounding the works has increased since their inception by no less than

44,000 inhabitants. The wages bill amounts, under normal conditions, to £1,750,000 per year. The original capital in 1885 was £304,000. The authorized capital in 1927 was £3,000,000, of which £2,687,708 had been paid up; the debentures outstanding stood at £1,518,600, the reserve fund at £1,535,000. (L. C. M.)

**BROKER.** In the primary sense of the word a broker is a mercantile agent, of the class known as general agents, whose office is to bring together intending buyers and sellers and make a contract between them, for a remuneration called brokerage or commission; e.g., cotton brokers, wool brokers, or produce brokers. Originally the only contracts negotiated by brokers were for the sale or purchase of commodities; but the word in its present use includes other classes of mercantile agents, such as stock brokers, insurance brokers, ship brokers, or bill brokers. Pawnbrokers are not brokers in any proper sense of the word; they deal as principals and do not act as agents. In discussing the chief questions of modern legal interest in connection with brokers we shall deal with them, first in the original sense of agents for the purchase and sale of goods.

**Relations Between Broker and Principal.**—In English law, a broker has not, like a factor, possession of his principal's goods, and unless expressly authorized cannot buy or sell in his own name; his business is to bring into privy of contract his principal and the third party. When the contract is made, ordinarily he drops out altogether. Brokers very frequently act as factors also, but, when they do so their rights and duties as factors must be distinguished from their rights and duties as brokers. It is a broker's duty to carry out his principal's instructions with diligence, skill and perfect good faith. He must see that the terms of the bargain accord with his principal's orders from a commercial point of view; e.g., as to quality, quantity and price; he must ensure that the contract of sale effected by him be legally enforceable by his principal against the third party; and he must not accept any commission from the third party, or put himself in any position in which his own interest may become opposed to his principal's. As soon as he has made the contract which he was employed to make, in most respects his duty to, and his authority from, his principal alike cease; and consequently the law of brokers relates principally to the formation of contracts by them.

The most important formality in English law, in making contracts for the sale of goods, with which a broker must comply, in order to make the contract legally enforceable by his principal against the third party is contained in Sec. 4 of the Sale of Goods Act, 1893, which (in substance re-enacting Sec. 17 of the Statute of Frauds) provides as follows:—"A contract for the sale of any goods of the value of ten pounds or upwards shall not be enforceable by action unless the buyer shall accept part of the goods as sold, and actually receive the same or give something in earnest to bind the contract, or in part payment, or *unless some note or memorandum in writing of the contract be made and signed by the party to be charged or his agent in that behalf*."

From the reign of James I. till 1884, brokers in London were admitted and licenced by the corporation, and regulated by statute; and it was common to employ one broker only, who acted as intermediary between, and was the agent of both buyer and seller. When the Statute of Frauds was passed in the reign of Charles II., it became the practice for the broker acting for both parties, to insert in a formal book, kept for the purpose, a memorandum of each contract effected by him, and to sign such memorandum on behalf of both parties, in order that there might be a written memorandum of the contract of sale, signed by the agent of the parties as required by the statute. He would then send to the buyer a copy of this memorandum, called the "bought note," and to the seller a "sold note," which would run as follows:—

"I have this day bought for you from A B [or, 'my principal']. . . . (signed) 'M, Broker'

"I have this day sold for you to A B [or, 'my principal']. . . . (signed) 'M, Broker'

There was in the earlier part of the 19th century considerable discussion in the courts as to whether the entry in a broker's

book, or the bought and sold notes (singly or together), constituted the statutory memorandum; and judicial opinion was not unanimous on the point. But brokers are no longer regulated by statute either in London or elsewhere, and keep no formal book; and as an entry made in a private book kept by the broker for another purpose, even if signed, would probably not be regarded as a memorandum signed by the agent of the parties in that behalf, the old discussion is now of little practical interest.

**Contract Notes.**—Under modern conditions of business the written memorandum of the contract of sale effected by the broker is usually to be found in a "contract note"; but the question whether, in the particular circumstances of each case, the contract note affords a sufficient memorandum in writing depends upon a variety of considerations—e.g., whether the transaction is effected through one or through two brokers; whether the contract notes are rendered by one broker only, or by both; and if the latter, whether exchanged between the brokers or rendered by each broker to his own client; for under present practice any one of these methods may obtain, according to the trade in which the transaction is effected, and the nature of the particular transaction.

Where one and the same broker is employed by both seller and buyer, bought and sold notes rendered in the old form provide the necessary memorandum of the contract. Where two brokers are employed, one by the seller and one by the buyer, sometimes one drops out as soon as the terms are negotiated, and the other makes out, signs and sends to the parties the bought and sold notes. The latter then becomes the agent of both parties for the purpose of signing the statutory memorandum, and the position is the same as if one broker only had been employed. On the other hand if one broker does not drop out of the transaction, each broker remains to the end the agent of his own principal only, and neither becomes the agent of the other party for the purpose of signing the memorandum. In such a case it is the usual practice for the buyer's broker to send to the seller's broker a note of the contract—"I, acting on account of A.B. [or, 'of my principal'] have this day bought from you, acting on account of C. D. [or, 'of your principal']"—and to receive a corresponding note from the seller's broker. Thus each of the parties receives through his own agent a memorandum signed by the other party's agent. These contract notes are usually known as, and serve the purpose of, "bought" and "sold" notes. In all the above three cases the broker's duty of and compliance with all formalities necessary to make the contract of sale legally enforceable is performed, and both parties obtain a written memorandum of the contract upon which they can sue.

The broker, on performing his duty in accordance with the terms upon which he is employed, is entitled to be paid his "brokerage." This usually takes the form of a percentage, varying according to the nature and conditions of the business, upon the total price of the goods bought or sold through him. When he guarantees the solvency of the other party, he is said to be employed upon *del credere* terms, and is entitled to a higher rate of remuneration. In some trades it is the custom for the selling broker to receive payment from the buyer or his broker; and in such case it is his duty to account to his principal for the purchase money. A broker who properly expends money or incurs liability on his principal's behalf in the course of his employment, is entitled to be reimbursed the money and indemnified against the liability. Not having, like a factor, possession of the goods, a broker has no lien by which to enforce his rights against his principal. If he fails to perform his duty, he loses his right to remuneration, reimbursement and indemnity, and further becomes liable to an action for damages and breach of his contract of employment at the suit of his principal.

**Relations Between Broker and Third Party.**—A broker who signs a contract note as broker on behalf of a principal, whether named or not, is not personally liable on the contract to the third party. But if he makes the contract in such a way as to make himself a party to it, the third party may sue either the broker or his principal, subject to the limitation that the third party, by his election to treat one as the party to the contract,

may preclude himself from suing the other. In this respect the ordinary rules of the law of agency apply to a broker. Generally, a broker has not authority to receive payment, but in trades in which it is customary for him to do so, if the buyer pays the seller's broker, and is then sued by the seller for the price by reason of the broker having become insolvent or absconded, he may set up the payment to the broker as a defence to the action by the broker's principal. Brokers may render themselves liable for damages in tort for the conversion of the goods at the suit of the true owner if they negotiate a sale of the goods for a selling principal who has no title to the goods.

**The Influence of Exchanges.**—The relations between brokers and their principals, and also between brokers and third parties as above defined, have been to some extent modified in practice by the institution since the middle of the 19th century in important commercial centres of "exchanges," where persons interested in a particular trade, whether as merchants or as brokers, meet for the transaction of business. By the contract of membership of the association in whose hands is vested the control of the exchange, every person on becoming a member agrees to be bound by the rules of the association, and to make his contracts on the market in accordance with them. A governing body or committee elected by the members enforces observance of the rules, and members who fail to meet their engagements on the market, or to conform to the rules, are liable to suspension or expulsion by the committee. All disputes between members on their contracts are submitted to an arbitration tribunal composed of members; and the arbitrators in deciding the questions submitted to them are guided by the rules. A printed book of rules is available for reference; and various printed forms of contract suited to the various requirements of the business are specified by the rules and supplied by the association for the use of members. In order to simplify the settlement of accounts between members, particularly in respect of "futures"; i.e., contracts for future delivery, a weekly or other periodical settlement, is on some exchanges effected by means of a clearing house; each member paying or receiving in respect of all his contracts which are still open, the balance of his weekly "differences"; i.e., the difference between the contract price and the market price fixed for the settlement, or between the last and the present settlement prices.

As all contracts on the market are made subject to the rules it follows that so far as the rules alter the rights and liabilities attached by law, the ordinary law is modified. The most important modification in the position of brokers effected by membership of such an exchange is due to the rule that as between themselves, all members are principals, on the market no agents are recognized; a broker employed by a non-member to buy for him on the market is treated by the rules as buying for himself, and is, therefore, personally liable on the contract. If it be a contract in futures, he is required to conform to the weekly settlement rules. If his principal fails to take delivery the engagement is his and he is required to make good to the member who sold to him any difference between the contract and market price at the date of delivery. But whilst this practice alters directly the relations of the broker to the third party, it also affects or tends to affect indirectly the relations of the broker to his own principal. The terms of the contract of employment being a matter of negotiation and agreement between them, it is open to a broker, if he chooses, to stipulate for particular terms; and it is the usual practice of exchanges to supply printed contract forms for the use of members in their dealings with non-members who employ them as brokers, containing a stipulation that the contract is made subject to the rules of the exchange; and frequently also a clause that the contract is made with the broker as *principal*. In addition to these express terms, there is in the contract of employment the term, implied by law in all trade contracts, that the parties consent to be bound by such trade usages as are consistent with the express terms of the contract, and reasonable. On executing an order the broker sends to his client a contract-note either in the form of the old bought and sold notes, "I have this day <sup>bought</sup> <sub>old</sub> for you,"

or when the principal clause is inserted, "I have this day sold to bought from you." These are not bought and sold notes proper, for the broker is not the agent of the third party for the purpose of signing them as statutory memoranda of the sale. But they purport to record the terms of the contract of employment, and the principal may treat himself as bound by their provisions. Sometimes they are accompanied by a detachable form, known as "the client's return contract note" to be filled in, signed and returned by the client; but even the "client's return contract note" is retained by the client's own broker, and is only a memorandum of the terms of employment. The following is a form of contract note rendered by a broker to his client for American cotton bought on the Liverpool Cotton Exchange for future delivery. The client's contract note is attached to it, and is in precisely corresponding form.

|--|--|
| <b>AMERICAN COTTON</b><br><i>Delivery Contract Note</i><br><b>LIVERPOOL..... 192</b> |  |
| Messrs. ....   |  |
| DEAR SIRS,   |  |
| We have this day..... to you, to be Delivered ex                                     |  |
| Warehouse in Liverpool during .....  |  |
| lb. AMERICAN COTTON net weight to be contained in                                    |  |
| AMERICAN BALES, more or less, on the basis   |  |
| of..... per lb. for .....  |  |
| The Contract, of which this is a note, is made between ourselves                     |  |
| and yourselves and not by or with any person whether disclosed                       |  |
| or not on whose instructions or for whose benefit the same may                       |  |
| have been entered into.  |  |
| This Contract is on "Settlement Terms" and is therefore subject                      |  |
| to Weekly Payments as provided for in the Rules.                                     |  |
| This Contract is subject to the Rules of the Liverpool Cotton                        |  |
| Association, Ltd., in force at the date of this contract which                       |  |
| provide (amongst other things) for the Settlement of differences                     |  |
| by Arbitration, and in case of any difference the matter shall be                    |  |
| settled in accordance with the Rules.  |  |
| This Contract shall not be cancelled on any ground.                                  |  |
| The Contract, of which the above is a note, was made on the                          |  |
| date specified within the business hours fixed in the Rules.                         |  |
| Yours faithfully,  |  |
| .....  |  |

The above form of contract note illustrates the tendency of exchanges to alter the relations between the broker and his principal. The object of inserting in the printed form the provision that the contract is made subject to the rules of the Liverpool Cotton Association is to make those rules binding upon the principal, and if he employs his broker upon the basis of the printed form, he does bind himself to any modification of the relations between himself and his broker which those rules may effect. The object of the principal clause in the above and similar printed forms is apparently to entitle the broker to sell to or buy from his principal on his own account and not as agent at all, thus disregarding the duty incumbent upon him as broker of making for his principal a contract with a third party.

Decisions of the court in recent years have tended to support the exchanges in imposing their own rules and usages on non-members doing business on the exchange, but the court would not support a provision in a contract which purported to entitle a broker to disregard his fundamental duties, as an agent, even although provided that both parties were principals. Arbitration clauses are, of course, also regularly supported by the courts, though the parties cannot oust the jurisdiction of the courts altogether; the provisions of the Arbitration Act enable a point of law to be brought before the courts by special case; and no agreement of the parties can deprive the court of its discretion under Sec. 4 of the act.

The tendency for the parties to contract as principals is prevalent on most exchanges, particularly in the case of contracts for the purchase and sale of goods for future delivery. This practice has many advantages because the parties to a contract know with whom they are dealing and are not affected by the subsequent disclosure of a principal. And it is generally found that it is possible

to maintain this position in practice without disturbing the fundamental relations of broker and client.

**Stockbrokers.**—A *stockbroker* is a broker who contracts for the sale of stocks and shares. Stockbrokers differ from brokers proper chiefly in that stocks and shares are not "goods," and the requirement of a memorandum in writing enacted by the Sale of Goods Act, 1893, does not apply. Hence actions may be brought by the principals to a contract for the sale of stocks and shares although no memorandum in writing exists. For instance, the jobber, on failing to recover from the buyer's broker the price of shares sold, by reason of the broker having failed and been declared a defaulter, may sue the buyer whose "name was passed" by the broker. The employment of a stockbroker is subject to the rules and customs of the stock exchange, in accordance with the principles discussed above, which apply to the employment of brokers proper. A custom which is illegal, such as the stock exchange practice of disregarding Leeman's Act, 1867, which enacts that contracts for the sale of joint-stock bank shares shall be void unless the registered numbers of the shares are stated therein, is not binding on the client to the extent of making the contract of sale valid. But if a client choose to instruct his broker to buy bank shares in accordance with that practice, the broker is entitled to be indemnified by his client for money which he pays on his behalf, even though the contract of sale so made is unenforceable. (*See STOCK EXCHANGE and STOCKBROKER.*)

**Insurance Brokers.**—An *insurance broker* is an agent whose business is to effect policies of insurance, including insurance treaties. He is employed by the person who has an interest to insure, pays the premium to the underwriter or insurance company, takes up the policy and almost invariably receives from the underwriter or company, payment in the event of a loss under the policy. By a custom which is invariable at Lloyd's, and practically so in the case of the companies, the broker is by custom responsible to the underwriter for payment of premium. The broker, although he is employed by the assured, is remunerated by a commission which the underwriter or company permits him to deduct from the premium. Insurances at Lloyd's can only be effected by brokers who are members of Lloyd's. It is an established practice for brokers to keep a current account with the underwriter or company; and premiums, losses and the broker's commission are dealt with in account. The broker usually conducts correspondence and negotiations on behalf of the assured, seeking to establish a right to recover a loss under the policy, but in the event of litigation the broker drops out, and the assured sues the underwriter or company direct. Agents, whether they effect life, fire, marine or other policies are known as insurance brokers if they are free agents and not bound in any way to one particular insurance. Lloyd's brokers are entitled by custom to 1% on the amount of the loss collected under marine policies.

**Ship-Brokers.**—These are first "commission agents," and secondly, very often also ships' managers. Their office is to act as agents for owners of ships to procure purchasers for ships, or ships for intending purchasers, in precisely the same manner as house agents act in respect of houses. They also act as agents for ship-owners in finding charterers for their ships, or for charterers in finding ships available for charter, and in either case they effect the charter-party. (*See AFFREIGHTMENT.*)

Chartering brokers are customarily paid by the ship-owner, when the charter-party is effected, whether originally employed by him or by the charterer. Charter-parties effected through brokers often contain a provision, "2½% on estimated amount of freight to be paid to A B, broker, on the signing of this charter-party, and the ship to be consigned to him for ship's business at the port of X [inserting the name of the port where A B carries on business]." The broker cannot sue on the charter-party contract because he is not a party to it, but the insertion of the clause practically prevents his right from being disputed by the ship-owner. When the broker does the ship's business in port, it is his duty to clear her at the customs and generally to act as "ship's husband."

**Bill-Brokers.**—*See BILL-BROKER.*

**United States Practice.**—The practice, and particularly the law, with respect to brokers in the United States coincide roughly

with the British conditions just described. There are some differences. Outside of New York agreements to arbitrate possible future disputes are not legally binding in the United States, and the highly developed arbitration feature of the British exchanges is not found, as yet. Neither is it common in the United States for the broker even on an exchange, to occupy, or undertake to occupy, the position of a principal with respect to his customer. Hence the accepted doctrine is that a broker cannot effectively, for his own account, sell to or purchase from his principal—subject always to the principal's knowledge and consent in any particular transaction. The rules of an exchange commonly and lawfully provide, however, that the same broker may act for a buyer and a seller in the same transaction, receiving a commission from each, provided that he first offer the sale publicly on the exchange at a fraction higher than his own prospective bid, and find no taker. Leeman's Act on sale of bank shares (of stock) is not law in the United States; on the other hand, in most States, and under the widely adopted Uniform Sales Act, a signed memorandum is as essential to the enforceability of the contract where the sale is of stocks or bonds as where it is of merchandise.

Bill-brokers are practically unknown in the United States; their general analogue is the note-broker. But the latter, instead of buying the paper of country banks and disposing of it in the metropolis, serves primarily as a retailer of paper to country banks, especially at times when the small bank's local demand for credit is not large. Typically the broker buys the notes, breaking the transaction up into a set of notes in round figures, so as to be able to reach the smaller banks; the notes run to the customer's own order and are blank endorsed, so as to be negotiable without endorsement by and obligation on the broker.

**Real Estate Brokers.**—Of considerable importance in both law and practice are also the real estate brokers. They commonly function differently from an agent, in that they do not themselves conclude the contract for their principal, but serve merely as negotiators who find another person willing to buy or sell, as the case may be, and persuade to the closing of a contract. Such a broker—who is commonly employed and paid by the seller—has earned his commission when he has produced a purchaser ready, willing and able to buy on the agreed terms, whether or not his principal sells to that purchaser. But prior sale by the principal or through another broker will defeat the broker's claim. Hence the present practice of brokers refusing to handle real estate unless they are given the exclusive agency or sale. Perhaps because of disputes as to the fact or terms of employment when a seller has met a purchaser in the presence of a broker, many states have passed statutes barring collection of a commission by a real estate broker unless he holds a contract of employment signed by his principal.

**BROMBERG** (Polish *Bydgoszcz*), a town of Poland, province of Poznan, 7m. from the Vistula, the centre of an important network of railways. Pop. (1900), 52,082; (1921), 87,800. The Bromberg canal connects the Brahe with the Notec, and thus establishes communication between the Vistula and Oder. The town has an active trade in agricultural products and is the chief centre of the Polish timber industries. Originally a border town between Poland and Pomerania, it suffered from the raids of the Teutonic knights. Restored by Casimir the Great in 1346, its commerce flourished, but declined in the 17th century. By the Treaty of Tilsit it became part of the grand duchy of Warsaw. In 1813 it was occupied by the Prussians, and was held by Prussia from 1815 to 1918.

**BROME, ALEXANDER** (1620–66), English poet, wrote many drinking songs and satirical verses in favour of the Royal-

ists and against the Rump. He published in 1661 *Songs and other Poems*, containing songs on various subjects, followed by a series of political songs, ballads, epistles, elegies and epitaphs, epigrams and translations. Izaak Walton wrote an introductory eclogue for this volume in praise of the writer, and his gaiety and wit won for him the title of the "English Anacreon" in Edward Phillips's *Theatrum Poetarum*. Brome published in 1666 a translation of Horace, by himself and others, and was the author of a comedy entitled *The Cunning Lovers* (1654). He also edited two volumes of Richard Brome's plays.

**BROME, RICHARD** (d. 1652), English dramatist, was originally a servant of Ben Jonson, and owed much to his master. The development of his plots, the strongly marked characters, and the amount of curious information to be found in his work, all show Jonson's influence. The relation of master and servant developed into friendship, and our knowledge of Brome's personal character is chiefly drawn from Ben Jonson's sonnet to "my old faithful servant and by his continued virtue my loving friend, Mr. Richard Brome," prefixed to *The Northern Lasse* (1632), the play which made Brome's reputation. The relation of master and servant did not necessarily imply lack of education on Brome's part; since Jonson expected his servant (see Epigram CI.) to read "a piece of Virgil, Tacitus, Livy or some better book to his friends at supper." Brome's genius lay entirely in comedy. He has left 15 pieces. *Five New Playes* (ed. by Alex. Brome, 1653) contained *Madd Couple Well Matchd* (acted 1639?); *Novella* (acted 1632); *Court Begger* (acted 1632); *City Witt*; *The Damselle or the New Ordinary*. *Five New Playes* (1659) included *The English Moor, or The Mock Marriage*; *The Love-Sick Court, or The Ambitious Politique*; *Covent Garden Weeded*; *The New Academy, or The New Exchange*; and *The Queen and Concubine*. *The Antipodes* (acted 1638, pr. 1640); *The Sparagus Garden* (acted 1635, pr. 1640); *A Joviall Crew, or the Merry Beggars* (acted 1641, pr. 1652, revised in 1731 as an "opera"), and *The Queenes Exchange* (pr. 1657), were published separately. He collaborated with Thomas Heywood in *The late Lancashire Witches* (pr. 1634). *A Joviall Crew* is generally considered the best of these. Brome's beggars have the true vagabond touch and the love of the road. It was the last play to be acted before the theatres were closed down in 1642 by order of the parliament.

See A. W. Ward, *History of English Dramatic Literature*, vol. iii. pp. 125–131 (1899), the article by Rev. Ronald Bayne in *Cambridge History of English Literature*, vol. vi., where there is an admirable account of Brome's work; and E. K. R. Faust, *Richard Brome* (Halle, 1887). *The Dramatic Works of Richard Brome* . . . were reprinted in 1873.

**BROMELIACEAE**, in botany, a family of Monocotyledons, confined to tropical and sub-tropical America; it consists of about 65 genera and 850 species. It includes the pineapple (*q.v.*) and also the so-called Spanish moss, a rootless plant, which hangs in long grey lichen-like festoons from the branches of trees, a native of Mexico and the southern United States; the water required is absorbed from the moisture in the air by peculiar hairs which cover the surface of the shoots. The plants are generally herbs with a shortened stem bearing a rosette of leaves and a spike or panicle of flowers. They are dry-country plants (xerophytes); the narrow leaves are protected by a thick cuticle, and have a sheath which embraces the stem and forms, with the sheaths of the other leaves of the rosette, a basin in which water collects, with fragments of rotting leaves and the like. Peculiar hairs are developed on the inner surface of the sheath by which the water and dissolved substances are absorbed. The leaf-margins are often spiny, and the leaf-spines of *Puya chilensis* are used by the natives as fish-hooks. Several species are grown as hot-house plants for the bright colour of their flowers or flower-bracts, e.g., species of *Tillandsia*, *Billbergia*, *Aechmea*. See illus. overleaf.

**BROMIDE**, chemically, a compound of bromine with an element or an organic radical, or a salt of hydrobromic acid, such as sodium bromide. Various bromides are of value in medicine, especially potassium bromide which is extensively used as a cardiac and cerebral depressant. From the application of the term bromide in the sense of a nerve sedative has arisen the colloquial

meaning of a bromide as a platitude; a person whose inane conversation bores excessively is called bromidic.

**BROMINE**, a deep red, liquid, non-metallic element of the halogen group, which takes its name from its pungent unpleasant smell (*βρωμος*, a stench). It was first recognized as an element and isolated by A. J. Balard in 1826 from the salts in the waters of the Mediterranean. It has the symbol Br, the atomic number

FROM "CURTIS' BOTANICAL MAGAZINE," BY PERMISSION OF THE ROYAL HORTICULTURE SOCIETY  
SLENDER HANGING BRANCHES OF SPANISH MOSS, A PERCHING PLANT WHICH HANGS IN FESTOONS FROM TREES IN THE SOUTHERN UNITED STATES AND TROPICAL AMERICA. (SEE PREVIOUS PAGE)

35, and the atomic weight 79.92. Bromine does not occur in nature in the uncombined condition, but in combination with various metals is very widely but sparingly distributed. Potassium, sodium and magnesium bromides are found in mineral waters, in river and sea-water, and occasionally in marine plants and animals. Its chief commercial sources are the salt deposits at Stassfurt in Prussian Saxony, in which magnesium bromide is found associated with various chlorides, and the brines of Michigan, Ohio, Pennsylvania and West Virginia, U.S.A.; a scheme is being developed for the extraction of bromides from the Dead Sea (1927).

**Manufacture.**—The chief centres of the bromine industry are Stassfurt and the central district of Michigan. It is manufactured from the magnesium bromide contained in "bittern" (the mother liquor of the salt industry), by two processes, the continuous and the periodic. The continuous process depends upon the decomposition of the bromide by chlorine, which is generated in special stills. A regular current of chlorine mixed with steam is led in at the bottom of a tall tower filled with broken bricks, and there meets a descending stream of hot bittern: bromine is liberated and is swept out of the tower together with some chlorine, by the current of steam, and then condensed in a worm. Any uncondensed bromine vapour is absorbed by moist iron borings, and the resulting iron bromide is used for the manufacture of potassium bromide. Commercial bromine is rarely pure,

the chief impurities present in it being chlorine, hydrobromic acid, and bromoform. It is usually purified by repeated shaking with potassium, calcium or ferrous bromide, and subsequent redistillation, a process which removes the chlorine and a part of the other impurities.

**Properties.**—Bromine at ordinary temperatures is a mobile liquid of fine red colour, which appears almost black in thick layers. It boils at 59°C., forming a deep red vapour, which exerts an irritating and directly poisonous action on the respiratory organs. It solidifies to a dark brown solid which melts at -7.3°C. Its specific gravity is 3.18828 ( $\frac{9}{4}$ ), latent heat of fusion 16.185 calories, latent heat of vaporization 45.6 calories, specific heat 0.1071. Its properties are altered to a remarkable degree by prolonged drying; a specimen which had been dried for eight years melted at -4.5°C. and boiled at 118°C., a rise of 60 degrees (H. B. Baker) (*see* DRYNESS, CHEMICAL). Bromine is soluble in water, to the extent of 3.226 grammes of bromine per 100 grammes of solution at 15°C., the solubility being slightly increased by the presence of potassium bromide. The solution is of an orange-red colour, and is quite permanent in the dark, but on exposure to light, gradually becomes colourless, owing to decomposition into hydrobromic acid and oxygen. By cooling the aqueous solution, hyacinth-red octahedra of a crystalline hydrate of composition  $\text{Br}_2 \cdot 10\text{H}_2\text{O}$  are obtained (Bakhuis Roozeboom). Bromine is soluble in chloroform, alcohol and ether.

Its chemical properties are in general intermediate between those of chlorine and iodine; thus it requires the presence of a catalytic agent, a fairly high temperature, or actinic light to bring about its union with hydrogen. It does not combine directly with oxygen, nitrogen or carbon. With the other elements it unites to form bromides, often with explosive violence; phosphorus detonates in liquid bromine and inflames in the vapour; iron is occasionally used to absorb bromine vapour, potassium reacts energetically, but sodium requires to be heated to 200°C. The chief use of bromine in analytical chemistry is based upon the oxidizing action of bromine water. Bromine and bromine water both bleach organic colouring matters. Bromine is used extensively in organic chemistry as a substituting and oxidizing agent, and also for the preparation of addition compounds. It is used in the liquid form, in vapour, in solution, and in the presence of the so-called "bromine carriers" (*see* below). The solvents in which bromine is employed are usually ether, chloroform, acetic acid, hydrochloric acid, carbon bisulphide or water. The choice of solvent and of other conditions is important, for the velocity of the reaction and the nature of the product may vary according to the solvent used, or according to whether the reaction is conducted in sunlight or not. The action of bromine is sometimes accelerated by the use of compounds which behave catalytically, the more important of these "carriers" being iodine, iron, ferric chloride, ferric bromide, aluminium bromide and phosphorus. For oxidizing purposes bromine is generally employed in aqueous and in alkaline solutions, one of its most important applications being by Emil Fischer, in his researches on the sugars. The most important determinations of the atomic weight of bromine are those of G. P. Baxter based on the ratios  $\text{Ag}:\text{AgBr}$ , and  $\text{AgCl}:\text{AgBr}$ ; and of P. A. Guye and E. Moles, based on the density of hydrogen bromide.

**Hydrobromic Acid.**—This acid,  $\text{HBr}$ , the only compound of hydrogen and bromine, is in many respects similar to hydrochloric acid, but is rather less stable. It may be prepared by passing hydrogen gas and bromine vapour through a tube containing a heated platinum spiral. It cannot be prepared with any degree of purity by the action of concentrated sulphuric acid on bromides, since secondary reactions take place, leading to the liberation of free bromine and formation of sulphur dioxide. The usual method employed for the preparation of the gas consists in dropping bromine on to a mixture of amorphous phosphorus and water, when a violent reaction takes place and the gas is rapidly liberated; an aqueous solution may be obtained by passing sulphuretted hydrogen through bromine water. At ordinary temperatures hydrobromic acid is a colourless gas which fumes strongly in moist air, and has an acid taste and reaction. It can

be condensed to a liquid, which boils at  $-68.7^{\circ}\text{C}$ . (under a pressure of 760 mm.), and, by still further cooling, gives colourless crystals which melt at  $-88.5^{\circ}\text{C}$ . It is readily soluble in water, forming the aqueous acid, which when saturated at  $0^{\circ}\text{C}$ . has a specific gravity of 1.78 and contains 82.02% HBr. When boiled, the aqueous acid loses either acid or water until a solution of constant boiling point is obtained, containing 48% of the acid and boiling at  $126^{\circ}\text{C}$ . under atmospheric pressure; should the pressure, however, vary, the strength of the solution boiling at a constant temperature varies also. Hydrobromic acid is one of the "strong" acids, being ionized to a very large extent even in concentrated solution, as shown by the molecular conductivity increasing by only a small amount over a wide range of dilution.

**Bromides.**—Hydrobromic acid reacts with metallic oxides, hydroxides and carbonates to form bromides, which can in many cases be obtained also by the direct union of the metals with bromine. As a class, the metallic bromides are solids at ordinary temperatures, which fuse readily and volatilize on heating. The majority are soluble in water, the chief exceptions being silver, mercurous, palladous and lead bromides; the last is, however, soluble in hot water. They are decomposed by chlorine, with liberation of bromine and formation of metallic chlorides; concentrated sulphuric acid also decomposes them, with formation of a metallic sulphate and liberation of bromine and sulphur dioxide. The non-metallic bromides are usually liquids, which are readily decomposed by water. Hydrobromic acid and its salts can be readily detected by the addition of chlorine water to their aqueous solutions, when bromine is liberated; or by warming with concentrated sulphuric acid and manganese dioxide, the same result being obtained. Silver nitrate in the presence of nitric acid gives with bromides a pale yellow precipitate of silver bromide, AgBr, which is sparingly soluble in ammonia. For their quantitative determination they are precipitated in nitric acid solution by means of silver nitrate, and the silver bromide is well washed, dried and weighed.

**Acids.**—No oxides of bromine have been isolated, but three oxy-acids are known, viz., hypobromous acid,  $\text{HBrO}$ , bromous acid,  $\text{HBrO}_2$ , and bromic acid  $\text{HBrO}_3$ . Hypobromous acid is obtained by shaking together bromine water and precipitated mercuric oxide, followed by distillation of the dilute solution *in vacuo* at low temperature (about  $40^{\circ}\text{C}$ .). It is a very unstable compound, breaking up, on heating, into bromine and oxygen. The aqueous solution is light yellow in colour, and possesses strong bleaching properties. Bromic acid is obtained by the addition of the calculated amount of sulphuric acid (previously diluted with water) to the barium salt; by the action of bromine on the silver salt, in the presence of water,  $5\text{AgBrO}_3 + 3\text{Br}_2 + 3\text{H}_2\text{O} = 5\text{AgBr} + 6\text{HBrO}_3$ , or by passing chlorine through a solution of bromine in water. The acid is only known in the form of its aqueous solution; this is, however, very unstable, decomposing on being heated to  $100^{\circ}\text{C}$ . in water, oxygen and bromine. By reducing agents such, for example, as sulphuretted hydrogen and sulphur dioxide, it is rapidly converted into hydrobromic acid. Hydrobromic acid decomposes it according to the equation  $\text{HBrO}_3 + 5\text{HBr} = 3\text{H}_2\text{O} + 3\text{Br}_2$ . Its salts are known as bromates, and are as a general rule with difficulty soluble in water, and decomposed by heat, with evolution of oxygen. Bromine forms compounds with fluorine ( $\text{BrF}_2$ ) and iodine ( $\text{IBr}$ ), but only a series of mixed crystals with chlorine.

**Applications.**—The salts of bromine are widely used in photography, especially bromide of silver. In medicine it is largely employed in the form of bromides of potassium, sodium and ammonium, as well as in combination with alkaloids and other substances.

**Medicinal Use.**—Bromide of potassium is the safest and most generally applicable sedative of the nervous system. Whilst very weak, its action is perfectly balanced throughout all nervous tissue, so much so that Sir Thomas Lauder Brunton has suggested its action to be due to its replacement of sodium chloride (common salt) in the fluids of the nervous system. Hence bromide of potassium (or bromide of sodium, which is possibly somewhat safer still though not quite so certain in its action) is used as a

hypnotic, as the standard anaphrodisiac, as a sedative in mania and all forms of morbid mental excitement, and in hyperaesthesia of all kinds. Its most striking success is in epilepsy, for which it is the specific remedy. It may be given in doses of from 10 to 50 grains or more, and may be continued without ill effect for long periods in grave cases of epilepsy (*grand mal*). Of the three bromides in common use the potassium salt is the most rapid and certain in its action, but may depress the heart in morbid states of that organ; in such cases the sodium salt (of which the base is inert) may be employed. In whooping-cough, when a sedative is required but a stimulant is also indicated, ammonium bromide is often invaluable. The conditions in which bromides are most frequently used are insomnia, epilepsy, whooping-cough, delirium tremens, asthma, migraine, laryngismus stridulus, the symptoms often attendant upon the climacteric in women, hysteria, neuralgia, certain nervous disorders of the heart, strychnine poisoning, nymphomania and spermatorrhoea. Hydrobromic acid is often used to relieve or prevent the headache and singing in the ears that may follow the administration of quinine and of salicylic acid or salicylates.

**BROMLEY, SIR THOMAS** (1530–1587), English judge born in Staffordshire in 1530, was educated at Oxford and called to the bar at the Middle Temple. Through family influence and the patronage of the lord keeper, Bacon, he made way in his profession, becoming recorder of London in 1566, and solicitor-general (1569). He sat in parliament successively for Bridgnorth, Wigan and Guildford. In 1579 he was made lord chancellor. As an equity judge he showed profound knowledge; Shelley's case (*q.v.*) is a landmark in English law. He presided at the trial of Mary, queen of Scots (1586), but the strain proved too much for his strength, and he died on April 12, 1587, and was buried in Westminster Abbey.

See Foss, *Lives of the Judges* (1848–64); J. Campbell, *Lives of the Lord Chancellors*.

**BROMLEY**, municipal borough of Kent, England, 10½ m. S.E. by S. of London by the Southern railway. Pop. (1931) 45,348. It lies on high ground north of the small River Ravensbourne in a well-wooded district, and has become a favourite residential locality for those whose business lies in London. The former palace of the bishops of Rochester (now a school) was erected in 1777 in place of an older structure. The manor belonged to this see as early as the reign of Ethelbert. In the gardens is a chalybeate spring known as St. Blaize's Well, which was in high repute before the Reformation. The church of St. Peter and St. Paul, mainly Perpendicular, retains a Norman font and other remains of an earlier building. Bromley college was founded by Bishop Warner in 1666 for "twenty poor widows of loyal and orthodox clergymen." In the vicinity of Bromley, Bickley is a similar residential township, and Hayes Common a favourite place of excursion. Bromley was incorporated in 1903, and is governed by a mayor, six aldermen and 18 councillors. Area 4,697 acres. The parliamentary borough of Bromley includes the urban districts of Beckenham and Penge, and had a population of 94,681 in 1921.

**BROMPTON**, a south-western district of London, England, in the south-east of the metropolitan borough of Kensington. Brompton road, leading south-west from Knightsbridge, is continued as Old Brompton road and Richmond road, to join Lillie road, at which point are the Metropolitan District and Southern Railway stations of West Brompton. Brompton Oratory, the Imperial institute, the Victoria and Albert museum, the Imperial College of Art, the Natural History museum, the Imperial Science museum, the Imperial College of Science and Technology, the offices of the University of London, the Brompton consumption hospital and the West London or Brompton cemetery are included in this district, which is mainly occupied by residences. (See KENSINGTON.)

**BROMSGROVE**, urban district, Worcestershire, England, 12m. N.N.E. of Worcester, with a station 1m. from the town on the Bristol-Birmingham L.M.S. line. Pop. (1931) 9,520. It lies in an undulating district near the foot of the Lickey hills. The railway towards Birmingham here ascends for 2m. one of

the steepest gradients in England over such a distance. There remain several picturesque half-timbered houses dating from 1572 and later. The church of St. John, mainly Perpendicular in date, is placed above the town. There is a well-known grammar school, founded by Edward VI. Birmingham sanatorium stands in the parish. Bromsgrove is a market town, but there are manufactures, *e.g.* of nails and buttons. The river Salwarpe works a number of mills in the neighbourhood. Near the town are L.M.S. railway carriage works.

**BRONCHIECTASIS** (*see also* RESPIRATORY SYSTEM, DISEASES OF), dilatation of the bronchi, a condition occurring in many diseases of the lungs. Bronchitis, both acute and chronic, chronic pneumonia and phthisis, acute pneumonia and broncho-pneumonia, may all leave after them a bronchiectasis whose position is determined by the primary lesion. Other causes are tracheal and bronchial obstruction, as from the pressure of an aneurism, new growth, etc. It is chiefly a disease of middle age, but may occur in debilitated children after measles, whooping cough, etc. The dilatation is cylindrical or saccular, and the medium and smaller sized tubes are generally affected, except where the cause is mechanical. The affection is usually of one lung only. Emphysema is a very common accompaniment. Cough is paroxysmal, and though severe is intermittent, the patient being entirely free for many hours at a time. The effect of posture is great. If the patient lie on the affected side, he may be free from cough the whole night, but if he turn to the sound side, or if he rise and bend forward, he brings up large quantities of foetid bronchial secretion. Where the dilatation is saccular it may come up in such quantities and with so much suddenness as to gush from the mouth. When the disease has lasted long, clubbing of fingers and toes is common. The diagnosis between this condition and a tuberculous cavity in the lung is often very difficult. Often the patient's condition can be greatly alleviated. Creosote vapour baths are eminently satisfactory. A mechanical treatment much recommended by some of the German physicians is that of forced expiration and, more recently, surgical drainage of the cavities has been adopted.

**BRONCHITIS**, the name given to inflammation of the mucous membrane of the bronchial tubes (*see* RESPIRATORY SYSTEM). Two main varieties occur, specific and non-specific. The bronchitis met with in typhoid fever and diphtheria, influenza, measles, pneumonia, due to the micro-organisms causing these diseases, is specific; that which results from extension from above, or from chemical or mechanical irritation, is non-specific. It is convenient to describe it, however, under the clinical divisions of *acute* and *chronic* bronchitis.
